20. ABSTRACT (Continue on reverse side if necessary and identity by block number)

This report describes the design and implementation of a relational database management system called INFOSAM. Its objective is to provide the INFOPLEX database computer project with a software test vehicle which could be used to gain insights into the Functional Hierarchy of the INFOPLEX database computer. Its design is largely based on Madnick's proposal for a hierarchically decomposed database management system. This implementation incorporates 3 levels which are primarily distinguished by their view of database

#### **ABSTRACT**

This thesis describes the design and implementation of a relational database management system called INFOSAM. design is largely based on Madnick's proposed design for a Database Management System <Madnick79>. Its design incorporates the concept of hierarchical decomposition, whereby the system is organized into levels or groups of modules which share a common function or view of the data. The levels are hierarchically related such that a given level is largely implemented through the services provided by the next lower level. INFOSAM incorporates 3 major levels, which are primarily distinguished by their view of the data. They are the External level, the Nset level and the Internal level. The objective of this stratification is to provide a high degree of data independence for the user, and a low level of functional redundancy in the system.

The objective of this thesis project was twofold. One objective was to implement a sample database management system that could be used as a teaching tool in classes on Database Management Systems. INFOSAM is small enough to be

comprehensible, yet it illustrates many of the key features of a full scale DBMS. The second objective was to provide the INFOPLEX project with a software test vehicle which could be used to gain insights into the Functional Hierarchy of the INFOPLEX DBMS. Hence, where possible its design reflected the proposed design for the Functional Hierarchy.

This thesis is organized as follows: Chapter 1 provides an introduction to the area of Database Management Systems, and sets the stage for the remaining chapters. Chapter 2 describes the relationship of INFOSAM to the INFOPLEX concept. Chapter 3 is a detailed overview of the design and implementation of INFOSAM. Chapter 4 summarizes the preliminary implications of INFOSAM for the INFOPLEX design. A sample terminal session is included in Appendix 1 and the complete listings for the system are included in Appendix 2.

I would also like to extend my thanks to my father, who through his inspiration and support made Sloan a reality.

Finally, I would like to thank my wife, Janie, for her unfailing support and cheerfulness during this last year. I count myself very lucky to have such a wonderful wife.

## Chapter 1

#### INTRODUCTION

Increasingly, information is being viewed as an important resource. It has been argued that the ability of a firm to effectively manage its information resource may provide it with an important competitive advantage in the coming years, particularly as other resources become increasingly more scarce. However, information is unlike any other resource available to the firm, in that the problem is not a scarcity of information but rather that there is often too much information. The problem has become one of organizing, and managing vast amounts of information, while at the same time shielding users from the complexity of managing the information, and allowing them to access information quickly and easily. This has necessitated the development of software and hardware tools with which to address this problem.

One such type of tool is the database management system (DBMS). A DBMS is specialized software system which is designed to shield the user from the complexity of the physical management of the information by acting as an interface

between the user and the data. While the DBMS is responsible for the actual physical management of the data, it usually provides the user with a capability to express actions on the database in terms of a conceptual data model, which may bear no resemblence to the manner in which the data is actually stored. For example, the DBMS may allow the user to view the database as a collection of tables. Any operation the user issues is expressed in terms of operations on these tables. It is the responsibility of the DBMS to translate operations expressed in such a manner into the corresponding operations on the database as it is physically implemented. The user never needs to know how the database is actually implemented. Hence, the user's view of the database need not change, even if the physical implementation changes.

There are other aspects of a DBMS worth noting, which focus more on the data management aspects. For example, the DBMS may provide security control, whereby only certain users may have access to particular types of data. On the otherhand, the DBMS may allow the sharing of data between different users. The DBMS may increase the reliability of the information. This results in part because the DBMS centralizes control over the data. This in turn may reduce the

redundancy of data, and hence the opportunity for inconsistent data values. In addition, the DBMS minimizes the redundancy of function among application programs, and this, in itself, increases reliability. A 100 different application programs can share the services provided by 1 search routine. Once that search routine has been debugged, there is no need to worry that application programs won't work because of an incorrect search routine.

There are currently many available Database Management Systems, and much work is being done in this area. For a description of some currently available systems see <Date> or <Cardenas> Key areas of research include, Concurrency control <Badal>, <Bernstein>; Multiple External views <Klug>; Security <Hsiao>; Database Machines <Madnick75, Madnick79, Madnick80>, <Hsaio77>; and Relational DBMS <Codd>, <Astrahan>, <Hall>. From the standpoint of a manager, a DBMS is probably the single most important systems program with which he need be familar. Hence, it will become increasingly important for managers to understand database management systems.

This thesis describes the implementation of a sample database management system called INFOSAM. INFOSAM is a

small scale relational database management system, designed and implemented as part of a Master's thesis at MIT's Sloan School of Management. The design of INFOSAM is based on Madnick's design for a DBMS called INFOPLEX (see <Madnick75>, <Madnick78>, <Hsu>). This approach incorporates the concept of a hierarchical decomposition of a DBMS, into levels or collections of modules which share a common function or view of the data. The levels are hierarchically related such that a given level is largely implemented via services provided by the next lower level.

The objective of this thesis is twofold. First, it is intended to be a sample database management system that could be used as a teaching tool in a course at Sloan on database management systems. The goal was to implement a system which was small enough to make it comprehensible as a case study, yet be sophisticated enough to illustrate the key features of a DBMS. For example, it illustrates how the Ansi/Sparc <Ansi/Sparc> concept of shielding the user's view of the database from the internal implementation of the database through the use of a conceptual level, might actually be implemented. It illustrates the different data models of the different levels and how the mapping between levels is achieved. At the same time, it illustrates a

range of things that are somewhat mundane, but nonetheless important. For example, how a character string key may be hashed into a location, how a scatter table and overflow chaining may be implemented, or how a command line can be lexically analyzed.

Second, it is intended to be a software test vehicle for the INFOPLEX project. INFOPLEX is a proposed design for a database machine which incorporates the concept of hierarchical decomposition. <Madnick75, Madnick78, Hsu>. As part of the design process, a software prototype was needed in order to further explore design issues. Since, the INFOPLEX design incorporates much of the current thinking regarding the desirable design of a DBMS, it was felt that the objective of developing a sample database management system could be met by implementing a small scale software prototype of the INFOPLEX functional hierarchy. This would allow it to be used as a software test vehicle for the INFOPLEX project as well as for a teaching tool.

Why is INFOSAM important? At the outset it should be noted that INFOSAM was primarily an engineering effort, rather than a research effort. The conceptual design of INFOSAM was largely derived from the previous work of Mad-

nick <Madnick79>, Hsu <Hsu>, Astrahan <Astrahan> and Senko <Senko>. Nonetheless, there are several aspects of INFOSAM which are worthy of mention.

- It is, if you will, a version 0 of the INFOPLEX functional hierarchy, and as such it provides an initial confirmation that the design of the functional hierarchy is basically sound.
- 2. A related point is that it clearly illustrates how the concept of heirarchical decomposition can be applied, in practice, to the design and implementation of a Database Management System.
- 3. The mapping technique used by the external level to process relational operations is potentially interesting and worth pursuing. While the concept is probably not unique to INFOSAM, it is probably one of the few actual implementations of such a technique.

The last point is that it has the potential to be a useful teaching tool. While it is somewhat complex, it could serve as a useful case study because it illustrates many key features of a full scale DBMS.

In chapter 2 we This thesis is organized as follows: discuss the context within which INFOSAM was developed so that the reader has some understanding why the system looks as it does. In particular, we will discuss the relationship of INFOSAM to the INFOPLEX project, its role in the project, how its role effected its design, and the major differences between INFOSAM and INFOPLEX. In chapter 3 we essentially walk the reader through the logical structure of INFOSAM. Here we discuss each level in INFOSAM in terms of its function, data model, databases and modules. The objective of this chapter is to not only give the reader an understanding of the logical structure of the system, but also illustrate how mapping between levels can be implemented and how the concept of a functional hierarchy has been implemented in the system. The last chapter summarizes what we have learned from the implementation of INFOSAM, both regarding the proposed design for INFOPLEX and for the current implementation of INFOSAM. In addition, there are 2 appendices. Appendix 1 illustrates a sample terminal session, and Appendix 2 contains the complete listings for the system.

## Chapter 2

## INFOSAM AND THE INFOPLEX PROJECT

While INFOSAM is a relational database management system in its own right, one of it's primary objectives was to serve as a software test vehicle for the INFOPLEX project. That is, as a software prototype of a proposed hardware configuration. Hence, much of INFOSAM's design is taken from the proposed INFOPLEX design for a DBMS. In this chapter we will provide the reader with an understanding of the context within which INFOSAM was designed and implemented so that the reader has some understanding why the system looks as it does. We will begin by introducing the concept of a software test vehicle, what it is, and why it might be used. We will then provide a very quick overview of the INFOPLEX concept, and its relationship to INFOSAM. In the next section, will outline design considerations that result from INFOSAM's relationship with INFOPLEX. Finally, we will highlight a few areas in which INFOSAM is different from INFO-PLEX and why. This last section is aimed primarily at those who are familar with INFOPLEX and want a quick summary of the major differences between the two systems.

## 2.1 THE ROLE OF INFOSAM AS A SOFTWARE TEST VEHICLE

A software test vehicle is best viewed as a software prototype of a system that may eventually be implemented all or in part via hardware. The software test vehicle (STV) is a collection of procedures which are organized in conceptually the same manner, and perform the same functions, as their hardware counterparts. Hence, the logical relationship and function of the modules is the same as in the proposed hardware configuration. In addition, the algorithms used by the software modules are as close as possible to those proposed for the hardware system.

The objective of a STV is to provide the system designer with a better understanding of the proposed system, and to allow him to test out various approaches before committing the system to hardware. Clearly, it is desirable to thoroughly understand a system prior to committing it to hardware, since mistakes at that stage can be very costly. A designer must understand not only the relationship of functional modules to each other but also the optimal internal structure of the functional modules. The STV concept aids the designer in both of these areas, by forcing him to implement a working software version of the system. Valuable lessons can be gained not only through the implementation

process, but also through a detailed performance analysis of the resulting system. The implementation process forces the designer to come to grips with how a particular function might actually be implemented. Often, the important but subtle implications of a design decision only come to light during the implementation process. In a similar fashion a performance analysis of the resulting system may bring to light issues that weren't readily apparent until the system was actually tested. Through the use of diagnostic code within the modules, detailed statistics may be collected and analyzed. Such measures may range from the number of times a particular module is called to service a request, to the amount of CPU time spent performing certain tasks. The designer can use these measures to identify better configurations, or more efficient algorithms.

However, an STV is not a static creation, and that is one of its great strengths. It provides the designer with a relatively flexible means of testing different configurations and different algorithms. Through the use of strictly defined uni-function modules, the designer can alter the configuration or modify the implementation of a particular module relatively quickly and easily. Thus, many different configurations can be tested and evaluated. This in turn

means that the system designer has little excuse for locking himself into a particular design without good reason.

Note, however, that the STV is just one stage in the design process. It is not a replacement for other stages of the process. Techniques such as Systematic Design Methodology (SDM) (see <Andreu>, <Huff>) are still essential for the preliminary design. Indeed, the STV should be based on the design suggested by SDM. Simulation techniques are also important tools for the designer, particularly when used in conjunction with STV. An STV can not be used to predict response times since the speed of the STV may bear no relation to the speed of the hardware configuration. For much the same reason a STV may not highlight bottlenecks in the system to the same degree that is possible through simulation techniques. Ideally, a simulation model would be used both before and after the use of an STV. Initially, it can be used in the preliminary design process, to give a rough idea of the system performance. During and after the STV stage the simulation model can be run again to give a much more accurate picture of the final system performance.

As the reader will see in the next section, INFOPLEX is a highly complex system, still very much in the design phase.

Ultimately, the system will be implemented via microprocessors. However, for many of the reasons discussed above there was a strong desire to build a software test vehicle to aid the design process. INFOSAM, was implemented, in part, to answer that need. Hence, much of the key design aspects of INFOSAM reflect the proposed design of the INFOPLEX system. In the next section, we will review the important aspects of the INFOPLEX design.

# 2.2 AN INTRODUCTION TO INFOPLEX

INFOPLEX was intially proposed by Madnick <Madnick 75> as a design for a database computer which incorporates the concept of a hierarchical decomposition of both function and hardware(<Madnick75>, <Madnick79>, <Hsu>). Hierarchical decomposition is a design and implementation strategy whereby a complex system is broken down into simplier subsystems, which are tightly defined, and hierarchically related to each other. That is, a given level, or subsystem is implemented making use of the services provided by the next lower level in the hierarchy. This approach has been shown effective in several software systems. to be (see <Madnick74> <Andreu77>, <Madnick79>) Indeed, a formal design called Systematic process, Design Methodology(<Andreu77>,<Huff>) has been developed around this concept.

INFOPLEX is composed of 2 hierarchically related subsystems, each of which, in turn, is hierarchically decomposed into levels. This is shown in table 1. The storage hierarchy is responsible for all storage and device managment (See <Madnick75> and <Madnick80> for a detailed discussion of the storage hierarchy). It is composed of a physical hierarchy of levels, where each level is composed of a type of storage device with a particular cost/performance tradeoff. Faster, but more expensive devices are at the top of the hierarchy, whereas cheaper, but slower, devices are at the bottom of the hierarchy. Information is moved automatically from level to level via algorithms implemented through microprocessors associated with each level. This movement of data is transparent to the functional heirarchy which sits on top of the storage hierarchy. As far as the functional hierarchy is concerned, memory consists of a huge virtual address space.

The Functional Hierarchy is responsible for all DBMS functions other than device management. It relies on the concept of a hierarchical decomposition based on both func-

TABLE 1
OVERVIEW OF INFOPLEX

#### FUNCTIONAL HIERARCHY

- \* Responsible for all DBMS functions except device and storage management.
- \* Functional hierarchy of modules

## STORAGE HIERARCHY

- \* Responsible for storage and device management.
- \* Physical hierarchy of storage devices.

tion and view of the data (see <Madnick79> and <Hsu> for detailed discussions of the Functional Hierarchy). Levels in the hierarchy are identified either by a specific function, such as data validity checking, or by a particular view of the data, such as the stored form of the data, versus the external or user's view of the data. This approach is similar to other attempts to stratify the design of a DBMS based on either function or view of the data (see <Ansi/Sparc>, <Astrahan>, and <Senko>). However, Madnick's approach is unique in that each level in the hierarchy is implemented via 1 or more microprocessors, which in turn rely on services provided provided by modules in the next lower level.

The decomposition of a DBMS as proposed by Madnick makes a great deal of sense for a number of reasons. For one thing, most transactions which are processed by a DBMS call for a common sequence of tasks. Hsu writes in this regard:

For example, it may first be checked by a security control module; then it is passed to a name-mapping module which determines the records to be accessed; and then it is given to a search module which determines the address of the records; finally a storage module is invoked to obtain the record from memory. These stages strongly suggest a database system structure that reflects their sequence. Moreover, the modules which support the earlier stages of processing (e.g., security control and name mapping) also require the services provided by those modules that support the later stages of processing (e.g., searching and accessing. <Hsu>

Another motivation for a hierarchical decomposition based on data model is that it allows the user's view of the data to be independent of the actual implementation by the lower levels. This means a user's view of the data need not change if the implementation changes. In addition, multiple external views of the database (i.e. relational, hierarchical or network) can be supported if the conceptual data model is flexible enough to support these multiple views. The conceptual data model of INFOPLEX is that of the binary network. A binary network is composed of Entities and Attributes, where an Entity is an object which is described by a set of attri-

butes, which may be either atomic values, or entities themselves. Madnick has proposed that such a structure is capable, given semantic information, of supporting multiple views of the data.<Madnick79>

Finally, another motivation for such a structure is that by its very design a functional hierarchy tends to minimize the redundancy of functions within the system. This in turn may increase reliability since functions are isolated within specific modules and can be more easily tested and debugged <Parnas>. Further, if an error occurs the problem can be isolated to a single module rather than requiring changes to multiple modules all of which employ the same logic.

In summary, INFOPLEX is a proposed hardware configuration for a database computer. The Functional Hierarchy, is the subsystem responsible for database functions. It views itself as sitting on a huge virtual address space, and is not concerned with device management. The Functional Hierarchy is designed around the concept of a functional hierarchical decomposition of a DBMS. The system is decomposed into levels which are collections of modules which either perform a common, but level specific function, or share a common data model. In addition, a level maintains its own

level-specific database used to perform its function. Each level is implemented via a cluster of microprocessors. The data models chosen were chosen on the basis of supporting multiple external views of the data and a flexible physical data structure.

INFOSAM was developed, in part, to be a software test vehicle for the functional hierarchy. In the next section, we will discuss the implications of this for the design of INFOSAM.

# 2.3 IMPLICATIONS OF INFOPLEX FOR THE INFOSAM DESIGN

The potential role of INFOSAM as a software test vehicle for the functional hierarchy subsystem of INFOPLEX had certain implications for its logical design as well as for it's actual implementation. These implications are outlined below.

The logical design of INFOSAM was to incorporate the concept of a functional hierarchy. On atleast a conceptual basis, the modules of the system were to be combined into levels. Levels were to be identified by either a specific function or by a particular data model and level specific databases. Modules in one level, could only call modules in

the level immediately beneath them. Where possible the levels would correspond to the levels identified by Hsu, and would incorporate the same data models as proposed by Hsu.<Hsu>

Since the functional hierarchy's view of storage was that of a virtual address space, and it was not concerned with device management, it was decided that INFOSAM could be implemented using in-core storage only. That is, INFOSAM was not required to access information from external devices.

Where possible communication between modules was to be done via bit string messages. This reflects the potential development of a message handling facility which would oversee and monitor the communication between modules of different levels. In addition, where possible, no pointers would be passed between levels. The idea being that only the lowermost levels should be aware of the physical location of the data.

In order to facilitate the use of the Software Test Vehicle, as well as to be consistent with the concept of a functional hierarchy, modules were to be strictly defined and unifunctional. The idea was that it should be easy to modify or completely change a module and 'plug' it into the system.

This also meant that a premium was to be placed on documentation standards.

## 2.4 MAJOR DESIGN DIFFERENCES BETWEEN INFOSAM AND INFOPLEX

There are several major design differences between INFOSAM and INFOPLEX. In most cases, the differences reflect limitations present in INFOSAM that would not be present in a full implementation of INFOPLEX. A few of the most important differences are described below. As mentioned earlier, this section is addressed toward those who are fairly familiar with the proposed design of the Functional Hierarchy.

One significant difference is in the number and definition of levels. As will be discussed in the next chapter, INFOSAM is composed of 3 levels, the Internal level, the Nset or Conceptual level, and the External level. The Internal level represents a union of Hsu's proposed Unary and Binary levels. The rationale for combining the levels was that in this implementation the Binary level was aware of the stored structure of the data, i.e. the BEU, and it required access to the equivalent of the unary set catalogue. As a result, it wasn't clear that the levels should be

separated. The Nset level is equivalent to Hsu's N-ary level, though on a reduced scale. The External level combines the View translation level, the View Enforcement level, and the Validity/Integrity level. The rationale for doing so was that only very primitive view enforcement and validity functions were implemented, so really our External

level represents the View translation level with some view enforcement and data validity functions embedded in it.

A second major difference is in the type of data models supported by the system, in particular, by the External and Nset levels. Only a single external view is supported, that being a relational view. This is in contrast to the INFOPLEX concept of multiple external views. A relational view was chosen for several reasons. From a user's standpoint its conceptually easy to understand, it supports ad-hoc queries, queries can be expressed in a simple yet powerful query language, and it is somewhat non-procedural. In addition, it has the advantage that the user does not need to know how his database is actually implemented. From a system standpoint, the relational data model is the easiest of the 3 traditional external views to map to the conceptual data model of the Nset level.

The data model of the Nset level is a very restricted form of the binary network proposed by Hsu. In Hsu's proposed data model, an entity could have another entity as one of its attributes, and this would be implemented as a binary association between instances of the entities. < Hsu> This allows her data model to be 'rich in semantics', that is, to be able to support a variety of external data models. However, the implementation of such a data model appears to be very complex. A modified binary network was implemented in INFOSAM, in which entities can share attributes, entity can not explicitly (i.e. be linked via a binary association) have another entity as an attribute. In addition, a given define or insert request may only reference 1 entity set, although a retrieval request may involve several entity sets. This restriction allows the Nset level to be much less complex. Since, this model is very close to the relational model, it is fully capable of supporting a relational external model. While the define and insert logic would have to be enhanced a great deal to support Hsu's model, the retrieval logic will probably require relatively few changes.

The points discussed above represent the significant conceptual differences between INFOSAM and INFOPLEX. There are

a few less significant differences which are worth noting. For one thing, the distinction between levels is totally conceptual. There is nothing in the system which prevents a module from calling any other module in the system. However, as currently implemented, modules in a given level only call modules in the level logically beneath it. Another difference is the manner in which binary sets are implemented. INFOPLEX supports 3 possible methods, pointer chaining, physical duplication, and physical embedding. INFOSAM only supports pointer chaining. This restriction was made primarily to simplify the implementation. INFOPLEX also makes the distinction between associative pointers and set pointers, and allocates different parts of the basic storage unit to store each type of pointer. In INFOSAM they share a common area. Finally, INFOPLEX allows an element in a unary set, to be in more than 1 primary set. Since, INFOSAM does not make a distinction between unary sets and primary sets, an element can only be in 1 primary set, though it can be in several subsets.

## 2.5 CONCLUDING REMARKS

While, INFOSAM can be viewed as a prototype of a DBMS without regard to the INFOPLEX project, an understanding of

the context in which it was designed is important to understand why certain design choices were made. This chapter, hopefully, has given the reader a sense of the context within which INFOSAM was designed and implemented. With this understanding in hand, we can now proceed to a detailed overview of the design and implementation of the INFOSAM system.

## Chapter 3

## LOGICAL OVERVIEW OF INFOSAM

The purpose of this chapter is to provide the reader with an understanding of the logical structure of INFOSAM. discussed in the previous chapter INFOSAM can be thought of as having three distinct levels. Each level has it's own data model, databases and collection of modules which are responsible for the definition, updating and retrieval of data items within the context of the level's view of the data. Our discussion of the logical structure of INFOSAM will center around a discussion of the separate levels. Thus for each level we will discuss, the conceptual data model used by the level, how the data model is implemented, the major databases used and maintained by the level, finally, a brief overview of the major modules which comprise the level. In general, we will skim over the implementation of the modules unless the implementation provides a useful insight into the logical structure of the system. The reader who is interested in a detailed discussion of the implementation is urged to consult the documentation and listing at the end of this report.

## 3.1 DESIGN OVERVIEW OF INFOSAM

While the design of INFOSAM is largely based on design proposed by the INFOPLEX project, it should be noted that it also makes use of concepts proposed by <a href="#">Ansi/Sparc</a>, <Senko</a>, and <a href="#">Astrahan</a>. In particular, the choice of 3 levels distinguished by data model, while consistent with the INFOPLEX design, is also based on the work cited above. In addition, the conceptual design and use of a basic storage element to build complex data structures via the elements and links between elements is similar to the strategy proposed by <Senko>

INFOSAM incorporates 3 levels, an External level which supports a relational view of the database, an Internal level which is responsible for actually storing and accessing the data, and a Conceptual level which acts to insulate the External level from the Internal level. Each level has it's own data model or view of the data. The External data model is that of the Relation. This means that it not only supports relational operations issued by a user but it views its own databases as relations and performs relational operations to manipulate the data in its databases. The External level is independent of the logical or stored structure of the data, and need not be changed if the Internal structure

of the data changes. The Conceptual level's data model is that of the Entity set. An Entity set is composed of a collection of objects or entities which are described by a common set of attributes. The Conceptual Level's view of the database is as it is logically organized. That is, it is aware of the information contained in the database, and the logical relationship of among Entities within the database. However, it is not aware of the physical organization of the data, nor of how the External level views the data. As with the External level, the Conceptual level views it's databases within the context of its data model, i.e. as being Entity sets. The Internal level's data model consists of Primitive sets and Binary sets. A Primitive set is a collection of elements which share some common property. A Binary set is a collection of binary associations between elements within two Primitive sets. The Internal level's view of the database is as the database is actually stored and represented. That is, it is aware of how elements with Primitive sets are physically stored, and how the associations among elements within a Primitive set or a Binary set are physically represented. However, it is not aware of how higher levels view the data.

Both the External and the Conceptual levels implement their data models via calls to the level immediately beneath them. These calls reflect the conceptual data model of the level being called, but do not depend on how that data model is actually implemented. Hence, a given level need only be aware of the data model of the level immediately beneath it and be able to map its conceptual data model to it. This provides a high degree of data independence within the sytem. The Internal level is the only level which must be aware of how it's conceptual data model is physically represented.

Table 2 provides a schematic view of INFOSAM. As can be seen from the table, INFOSAM is composed of 3 levels: the External level, the Nset level, and the Internal level. The Internal level is further decomposed into 2 layers: the Primitive or Pset layer and the Binary or Bset level. A level is distinguished by a) a level specific data model, b) level specific databases, and c) modules necessary to maintain it's data bases and implement it's data model (albeit via calls to modules in the level beneath it). The Internal level is broken down into 2 layers because while the layers share common databases and routines they use different data models. It should be noted that this decomposition is tran-

sparent to the Nset level, which only sees a unified Internal level. In keeping with the concept of the functional hierarchy modules in one level may only call modules in it's own level or the level immediately beneath it.

TABLE 2
Schematic Overview of Infosam

	EXTERNAL LEVEL	
	NSET LEVEL	
	INTERNAL LEVEL Bset Layer Primitive Layer	

In the following sections we will discuss each level in term's of its data model and it's major responsibilities.

Once we have presented this overview we will go back and discuss the implementation in greater detail.

## 3.2 THE INTERNAL LEVEL

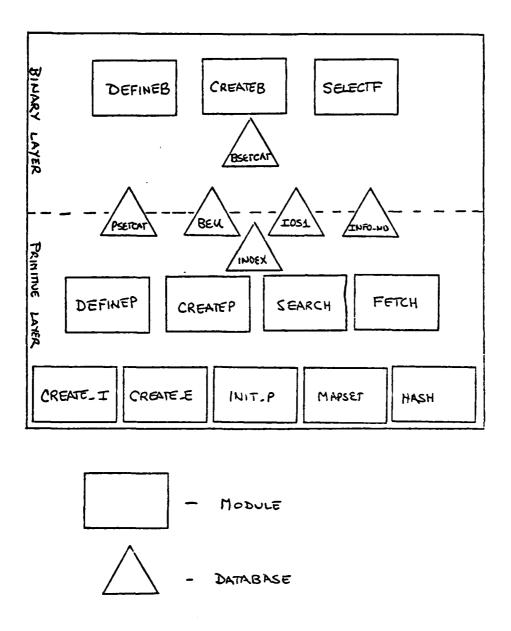

The Internal level is the lowest level in the system. It is concerned with the actual storage, and retrieval of data items, as well as maintaining associations among data elements which are either logically similar or logically related, and being able to retrieve associated data elements given a definition of the association. The Internal level shields the Conceptual level from needing to know how data items are stored or linked, and thus makes the Conceptual level somewhat independent of the actual implementation of the Internal level. At the same time the Internal level provides the Conceptual level with a data model which allows the Conceptual level to be able to express reasonably complicated data structures.

Table 3 provides a schematic view of the modules and databases of the Internal level.

The Internal level is composed of 2 layers which are hierarchically related, the Primitive or Pset layer and the Binary or Bset layer. The Primitive layer is unaware of the Binary level, whereas the Binary level relies heaviliy on the data model of the Primitive layer. While the layers have different data models, they share common databases and hence

TABLE 3

Modules and Databases of the Internal Level

do not warrant being distinguished as separate levels. Note, this is in contrast to the approach taken by Hsu <Hsu>, in which the Unary and binary levels are viewed as separate levels. As implemented here, both the Primitive and Binary layers require knowledge of the stored form of the data since linkage information is stored with the data element. In addition, they both share the same linkage information area in the basic storage unit. Hence, its not clear how the Binary layer could be isolated from the stored form of the data. However, in order to simplify our discussion of the Internal level we will discuss the layers separately.

## 3.2.1 The Primitive layer

The conceptual data model of the Primitive layer is the Primitive set. A Primitive set is a collection of elements which share some common property. For example, a Primitive set could be composed of a collection of supplier's names, the common property being that the data elements represent the names of your suppliers. Note, that the interpretation of a Primitive set is external to the set. That is, what you view as a set of supplier's names may be viewed by someone else as a Primitive set comprised of 8-byte character strings. A Primitive set can be either a Primary set, or a

subset. By a subset we mean that it is a subset of another Primitive set. For example, a set containing the names of all students at MIT might be considered a Primitive set as well as a Primary set. That Primitive set, in turn, contains a subset which represents the names of all students at the MIT Sloan School of Management. That subset is also a Primitive set in that it's elements share a common property. A Primary set is a Primitive set which is not a subset of another Primitive set. Conceptually, there is no reason why a subset could not also contain subsets. However, in this implementation, subsets can not contain subsets.

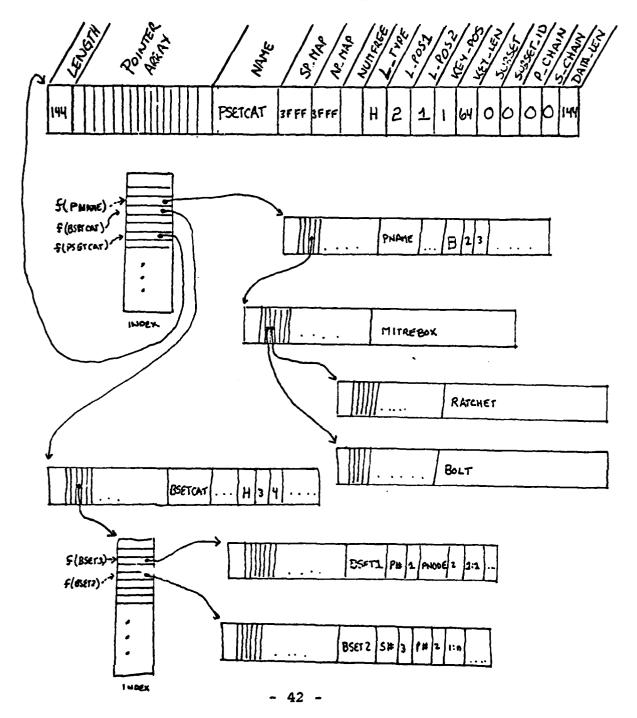

The purpose of the Primitive set layer is to accept calls to perform actions on its conceptual data model (i.e. define pset, insert pset, retrieve pset), map those requests to actions on the phsical representation of its data model, and actually perform the required actions. Unlike the other levels, it is also responsible for implementing the physical representation of its data model. In the following section we will briefly discuss the logic of the Primitive layer and then elaborate on the layer's databases and routines.

All stored information in the system is stored in based structures called Basic Encoding Units (BEU). A BEU consists

of a pointer array, which is used to hold linkage information, and a bit string data area which is used to hold the actual data. A Primitive set is implemented as a set of BEUs which hold the actual elements of the Pset and an additional BEU which contains information concerning the organization of the pset (i.e. how elements are linked, location of key field, etc.). The BEU which describes the Pset's organization is also part of a Pset called PSET CAT which is a Primitive set consisting of all the BEUs which describe Psets in the system. Hence, that BEU is referred to as the PSET CAT catalogue entry for the Pset. This is illustrated in Table 4 . Any action on a Pset first requires the retrieval of the PSET CAT catalogue entry in order to know know how the Primitive set is implemented. The only exception to this is the define action. In this case the major task of the define module is to create the PSET\_CAT entry for the pset.

Linkage among elements in a Pset is accomplished in one of three ways: (1) hashing via a scatter table and overflow chaining,(2) as a B-tree, or (3) via simple linear chaining. Each of these methods are illustrated in tables 5 - 7 If simple linear chaining is used, a pointer slot in the p\_array of the Pset's BEUs is reserved to be used for Pset chaining. In addition, a pointer slot in the P\_array of the

TABLE 4
Organization of the PSET\_CAT Pset

catalogue BEU is reserved to point to the last element inserted into the Pset. When an element is inserted into the Pset the pointer to the last element in the Pset is placed in the reserved pointer slot of the BEU which contains the newest insertion to the Pset, and the pointer slot in the catalogue entry is updated to point to the new element. On retrieval, the catalogue entry is fetched and the pointer chain is followed until the desired element is found or until the pointer slot contains a null value.

B-tree linkage is very similar except that 2 pointer slots are reserved to be used for Pset chaining, and the pointer slot in the PSET\_CAT entry for the Pset points to the first element in the set. When an element is to be inserted the existing B-tree for the Pset must be searched to find the node (i.e. BEU) to which the new BEU should be chained. Chaining is accomplished by setting the appropriate pointer slot in that node so that it points to the new element.

If hashing is to be used, a based structure is created at Pset definition time to act as a scatter table for the Pset, and a pointer slot in the catalogue BEU for the Pset is updated to point to the scatter table. In addition, a poin-

TABLE 5

Example of Linear Chaining

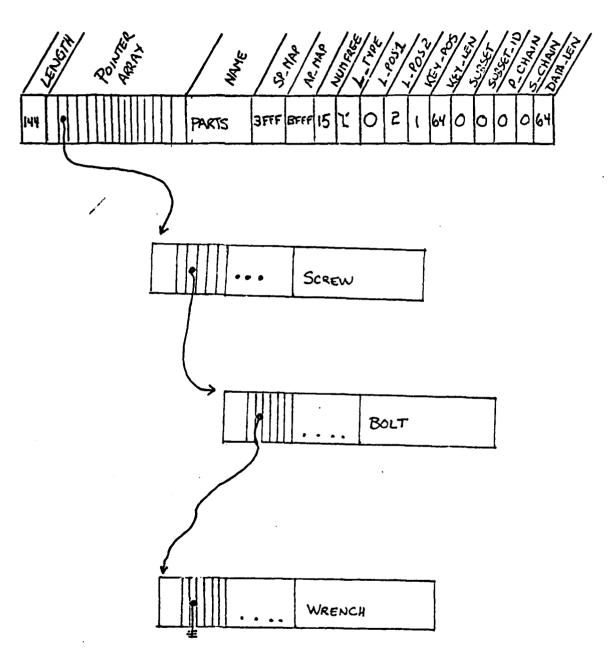

TABLE 6
Example of B\_tree linkage

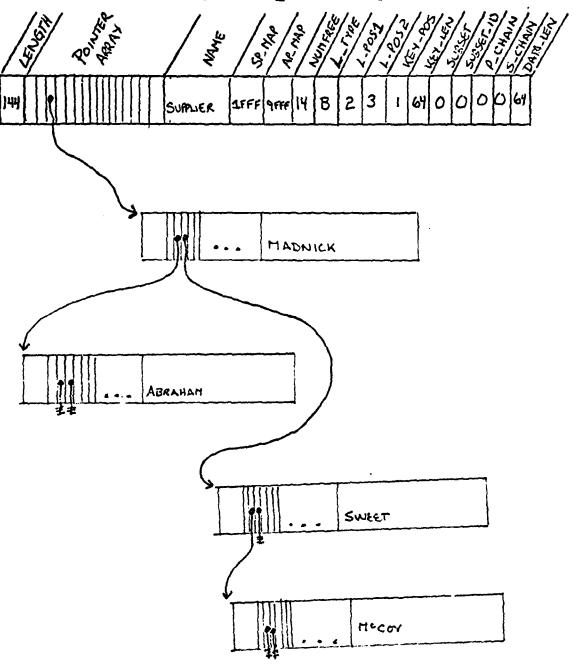

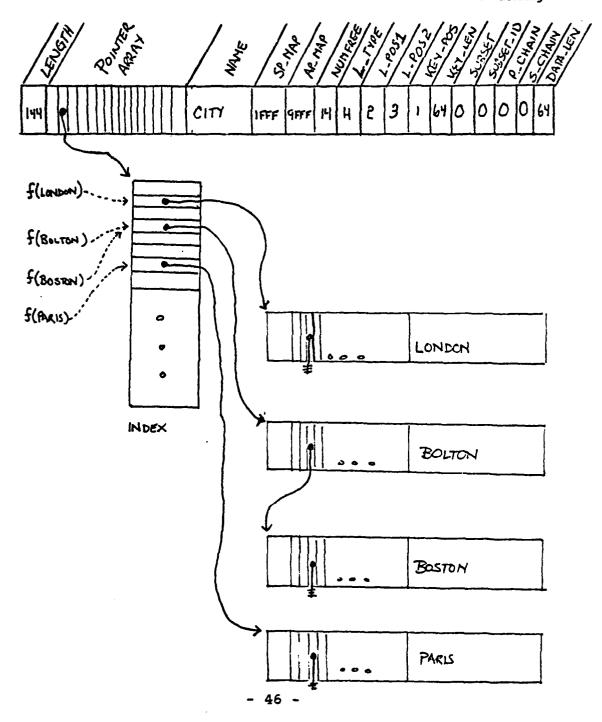

TABLE 7

Example of Hashing via Scatter Table and Overflow Chaining

ter slot is reserved in the Pset's BEUs to be used for overflow chaining. When an element is to be inserted the catalogue entry for the Pset is first fetched and the location of the scatter table is found. The key in the element to be inserted is then hashed via a system hash function and the corresponding element in the scatter table is checked to see whether it is null. If it isn't, then the element in the scatter table is updated to point to the new BEU in the Pset. Otherwise, the pointer slot in the new BEU which was reserved for overflow chaining is updated to point to the element specified in the scatter table, and the element in the scatter table is updated to point to the new BEU. retrieval, the catalogue entry is fetched and the location of the scatter table is found. The key is then hashed and the corresponding location in the scatter table is checked. If it isn't null, then the contents of the BEU pointed to by the entry in the scatter table is checked to see if it matchs the key. If it doesn't then the overflow chain is followed until either the desired element is found or a null value is found in the pointer slot reserved for overflow chaining.

The implementation of the Pset layer involves 3 major databases and 4 major modules. In the next section we will

briefly outline the structure of the databases and the logic of the modules.

# 3.2.2 Databases of the Primitive Layer

The Primitive layer makes use of 3 databases: (1) the BEU, (2) the PSET\_CAT, and (3) the Index databases. These will be outlined below.

#### 3.2.2.1 BEU

All stored information in the system is stored in based structures called Basic Encoding Units. A BEU contains the data value as well as linkage information. Formally, a BEU is declared as follows:

- 1 BEU BASED(ID),
  - 2 LENGTH FIXED BIN(15),
  - 2 P ARRAY(16) POINTER,
  - 2 INFO BIT(320);

where the elements are interpreted as follows:

ID - Each allocation of a BEU has a unique ID, by which it can be referenced. This ID corresponds to the pointer value on which the structure is based at the time the structure is allocated. A BEU can be accessed by overlaying a BEU

structure on a location in memory pointed to by the ID.

Note, however, that the ID is not stored in the BEU, but
serves as an External reference to it.

LENGTH - The length field is used to specify the length of actual data in INFO. Since Info is a fixed length string, it may contain a a data element whose length is less than that of Info. Hence, the need to specify the length. Note, in a later implementation the length of Info would probably be variable and LENGTH in that case would be the length of the Info field.

P\_ARRAY - This is a pointer array which is used to contain linkage information. Both the Pset and Bset layers use the pointer slots in P\_ARRAY to implement their respective linkages. Typically, at set definition time (be it a Pset or a Bset) the definition module reserves a pointer slot to be used to implement the linkage being defined. By reserve, we mean that a flag is set in the PSET\_CAT entry for the Pset indicating that that pointer slot in BEUs containing elements of the Pset is reserved for a specific purpose. In addition, the PSET\_CAT or BSET\_CAT entry will contain information on how the contents of the pointer slot are to be interpreted. The P ARRAY is of fixed size to simplify

implementation. However, this does limit the number of linkages that can be implemented.

INFO - This is a fixed length bit string which holds the data to be stored. A bit string representation was chosen to make the BEU generalizable and to allow common routines to be used regardless of the type of information contained in the BEU. It is fixed length to simplify implementation.

The BEU is a powerful structure that allows a single data element to take on more than one meaning through it's linkages. In addition, it supports the creation of complex and varied data structures, and once again a single instance of a data element may be a part of different data structures. It is not without it's drawbacks, however. In particular, a single BEU, as implemented in this system, requires over 100 bytes regardless of the amount of information it contains. If, however, the size of the pointer array and the data area was determined dynamically, then this problem would be somewhat reduced.

## 3.2.2.2 PSET CAT

Every Primitive set defined by the system contains a BEU which describes the implementation of the Pset, i.e. how the

BEUs which contain the elements of the Pset are linked and how they are to be interpreted. This BEU is in turn a member of a Primitive set called PSET\_CAT which is the set of all BEUs used to describe the implementation of Psets in the system. That set is in fact a catalogue of all the Primitive sets in the system. The entire BEU is used as the catalogue entry by overlaying the following structure on any BEU which contains a catalog entry.

```
1 CAT_ENTRY BASED(P),
```

- 2 LENGTH FIXED BIN(15),
- 2 P\_ARRAY(16) POINTER,
- 2 DATA
  - 3 NAME BIT(64),
  - (3 SP\_MAP,
  - 3 AP\_MAP) BIT(16),
  - 3 NUMFREE BIT(8),
  - 3 SEARCH\_INFO
    - (4 L\_TYPE,
      - 4 L POS1,
      - 4 L\_POS2,
      - 4 KEY\_POS,
      - 4 KEY\_LEN ) BIT(8),
  - 3 SET\_TYPE
    - (4 SUBSET,

- 4 SUBSET\_ID,
- 4 P\_CHAIN,
- 4 S\_CHAIN) BIT(8);

where the elements of the catalogue are interpreted as follows (Note, the reader may find it useful to refer to tables 5 - 7 during this discussion for examples of how the fields of the catalogue are in fact used.):

LENGTH - Used to specify the length, in bits, of the catalogue entry.

P\_ARRAY - Contains linkage information used to link the catalogue entry to the elements in the pset (either directly or via a pointer to a scatter table), or to link the catalogue entry to other related catalogue entries (for example, all catalogue entries for a Primary set and any subsets of it are chained together). The contents of the pointer slots within P\_ARRAY are interpreted depending on the contents of Search\_Info.

NAME - The name of the Pset being described.

SP\_MAP & AP\_MAP - These bit strings are used as maps to indicate the status of the pointer slots in the P\_ARRAYs of the BEUs within the Pset. Each map has 16 bits correspond-

ing to the 16 pointer slots in a P array. A 'l'b indicates that the pointer slot is available for use, whereas a '0'b indicates that the pointer slot has been reserved. When the Pset definition module needs to reserve a pointer slot in the BEUs it calls a routine which finds the first '1'b in the SP\_MAP, sets it and the corresponding bit in AP\_MAP to '0'b and returns the position of the bit to the define routine. This represents the position of the pointer slot being reserved. A similar procedure is used to reserve pointer slots in order to implement linkages in BSETs, except that the AP MAP is searched first. The reason 2 maps are used rather than 1 is that certain pointer slots are not available for Pset linkage, but are available for Bset linkages. For example, pointer slot 1 is used for overflow chaining in the PSET CAT Pset and is unavailable for other Pset linkages, but it is available for Bset linkages. This non-symmetry results from the fact that the position of the pointer slots linking the PSET CAT entries to their elements is the same as the position of the pointer slots linking the elements to each other. Since pointer slot 1 is already allocated to overflow chaining within the PSET CAT Pset, it can not be used to chain catalogue entries to their elements.

NUMFREE - number of available pointer slots left in BEUs of Pset.

L\_TYPE - Specifies the access method used to locate elements within the Pset. This can be either Hashed, B\_tree or linear chaining.

L\_POS1 - Specifies pointer slot used to implement the Pset linkage among BEUs which contain elements of the Pset. Exact meaning depends on the type of linkage implemented. If hashed, then refers to pointer slot in PSET\_CAT entry which points to the scatter table. If B\_tree, then refers to the pointer slot in the BEUs of the set used to chain right descendents of the B\_tree. If linear used, L\_POS1 not used.

L\_POS2 - also used to specify pointer slots used for Pset linkages. Exact meaning also depends on type of linkage implemented. If Hashed, then it is used to specify pointer slot used for overflow chaining. If B\_tree, then it is used for a dual purpose. First, it specifies the pointer slot in the PSET\_CAT entry used to point to the first element in the Pset. Second, the same pointer slot is used to chain left descendents among BEUs of the Pset. Finally, if Linear, then it specifies the pointer slot used for chaining the PSET\_CAT entry to the last BEU in the set as well as for chaining BEUs of the Pset together.

KEY\_POS - specifies starting location of the key within the INFO field of the BEUs containing the data elements.

KEY\_LEN - specifies length of the key within the INFO field.

SUBSET - flag to indicate if this Pset is a Primary set or a subset.

SUBSET\_ID - If Pset is a subset, then this element indicates the pointer slot used for chaining elements of the subset together. As currently implemented, subset linkages are all implemented via linear chaining. Note, if subsets are exclusive, then subsets can share a common subset\_id.

P\_CHAIN - If Pset is a subset, then this element specifies the pointer slot in the PSET\_CAT entry used to point to the Primary Pset PSET\_CAT entry. This information is required to implement insertions and deletions correctly within both the Primary set and it's subsets.

S\_CHAIN - If Pset is a subset, then this element is used to specify the pointer slot in the PSET\_CAT used to chain catalogue entries for all subsets within a given Primary set. Simple linear chaining is used.

## 3.2.2.3 INDEX

As discussed earlier, hashing is implemented via a scatter table and overflow chaining. When the link type is specified as hashed, the Pset definition module allocates the follwoing structure to act as a scatter table for the Pset:

- 1 INDEX BASED(INDEX PTR),
  - 2 NAME\_ENTRY BIT(64),
  - 2 TEST LEN FIXED BIN(15),
  - 2 PTR\_TO\_ENTRY(50) POINTER;

Where the elements are interpreted as follows:

INDEX\_PTR - specifies the pointer value on which this structure is based. Once allocated the value of INDEX\_PTR is placed into the L\_POS1 pointer slot in the catalogue entry for the Pset.

NAME\_ENTRY - indicates the name of the Pset for which this is a scatter table. Note, this field serves no real purpose and could be eliminated in a later implementation.

TEST\_LEN - specifies the length in bits of the key field in the BEUs of the pset to be used in determining the hash value.

PTR\_TO\_ENTRY - This is a pointer array which acts as a scatter table for the Pset. An element of this pointer array is null or points either to the first element whose key hashed to that location, or to the beginning of an overflow chain of BEUs which hashed to that same location. For efficiency reasons, elements are inserted at the beginning of the overflow chain rather than at the end. Hence, the beginning of the overflow chain is, in fact, the last element to be added to that overflow chain.

# 3.2.2.4 Temporary Databases Built by Primitive Layer

There are two other databases of significance which the Primitive Layer builds in order to return values to higher layers or levels. These databases are temporary stacks built by the Primitive layer and destroyed by the upper levels once they have examined the contents of stack. The first of these databases is called IDS1, and it is used to return the IDs of elements found by the SEARCH module. It is declared as follows:

## IDS1 POINTER EXTERNAL CONTROLLED;

The second of these databases is called INFO\_ND, and it is used to return the data portion of BEUs within a Pset. It is created by the FETCH module. Its formal declaration is as follows:

INFO ND BIT(320) EXTERNAL CONTROLLED;

A stack structure was chosen because of the dynamic nature of the number items that might be returned, and because implementation via the controlled attribute makes management of the databases fairly simple.

# 3.2.3 The Modules of the Primitive Layer

The Primitive layer consists of 4 major modules, and 5 support modules. These modules are responsible for the physical implementation of the Pset data model. In this section we will briefly outline the purpose of each module, and where appropriate discuss the logical structure of the modules. The reader is urged to consult the documentation in Appendix 1 for a detailed discussion of the Internal structure of the modules.

#### 3.2.3.1 DEFINEP

This module is responsible for creating a PSET\_CAT catalog entry for each Primary set and Subset defined in the system. In addition, it is responsible for reserving pointer slots to be used for Pset linkages, as well as creating support structures if necessary (i.e. INDEX if the Pset is to be hashed). In order to define a Pset, DEFINEP requires par-

ameters which specify the name of the Pset, the desired access or linkage method, the position and length of the key, and if it is a subset of a Primary set it needs to know the name of the Primary set and the pointer slot to be used for subset linkage. The logic of DEFINEP is fairly simple. If this is the first Pset to have been defined, the INIT P module is called which defines the PSET CAT Pset and inserts a catalogue entry into the Pset which describes the organization of the PSET CAT. Otherwise, a temporary structure is allocated to serve as a template for the new catalogue entry. If the Pset to be defined is a Primary set, then this template is simply a copy of the PSET CAT entry describing the PSET CAT Pset. Otherwise, the template is a copy of the PSET\_CAT entry for the Primary set for which this is a sub-In this manner the Subset organization is made to reflect the organization of the Primary set. The module then proceeds to build the catalogue entry to reflect the parameters passed to it. If pointer slots need be reserved, then the MAPSET module is called to analyze the appropriate map in the catalogue entry, find the first available pointer slot, and return that value as well as update the maps. Once the catalogue entry is built, the Data portion of the catalogue entry is passed to CREATEP which is responsible

for actually creating the BEU which will contain the catalogue entry, and for inserting that BEU into the PSET\_CAT Pset. The final task is to update the pointer slots of the newly created BEU. If the link type is hashed, then the CREATE\_I module is called to create a scatter table for the Pset, and a pointer to that scatter table is placed into the appropriate pointer slot in the catalogue entry. If the Pset is a subset, then it is also necessary to chain the subset definition to both the Primary set definition and any other subset definitions for that Primary set. In addition, the SP\_MAP and AP\_MAPs of the Primary set must be updated to reflect any additional pointer slots which are no longer available for use.

## 3.2.3.2 CREATEP

This module is responsible for inserting an element into a previously defined Pset, given the name of the Pset and a bit string representation of the data. In order to accomplish this, this module must perform several tasks. First, it must retrieve the PSET\_CAT entry for the Pset. This is done via a call to the SEARCH module, passing it PSET\_CAT as the Pset to search and the name of the Pset as the key to search on. The next task is to create a BEU which contains

the bit string representation of the data. This is accomplished via a call to the CREATE\_E module which actually creates a BEU and inserts the data into the newly created BEU. The final task is to insert the BEU into the Pset in accordance with the link type specified in the PSET\_CAT entry for the Pset. This is done via a call to the CHAIN module which inserts the BEU into the Pset, taking into account the organization of the Pset, and the contents of the BEU to be inserted. If the Pset is a subset, then CHAIN is called a second time to insert the BEU into the Primary set.

#### 3.2.3.3 SEARCH

This module is responsible for retrieving the IDs of one or more elements in a Pset given the name of the Pset, the retrieval mode and a key to search on if necessary. The SEARCH module supports 3 modes, 1) First element in set which matches key, 2) All elements in set which match key, and 3) All elements in set. It returns a stack which contains the IDs found. The SEARCH module is, in fact, composed of 6 specialized Internal search routines which are called depending on the Pset organization and the retrieval mode. The logic of the SEARCH module is as follows. The first task

is to fetch the PSET CAT entry for the Pset. This is done by first retrieving the PSET\_CAT entry for the PSET\_CAT Pset, and then by calling the appropriate search routine given the organization of the PSET\_CAT specified in it's catalogue entry and the name of the Pset. If the mode is either (1) or (2) then the appropriate search routine is called (i.e. L SEARCH, B SEARCH, or H SEARCH). L SEARCH is a simple linear search which returns the ID of the first element which contains a match with the key. It, like all of the search modules, relies on the PSET\_CAT entry for the Pset for information concerning which pointer slots are used for chaining, how the contents of those pointer slots are to be interpreted, and the position and length of the key. B\_SEARCH performs a Binary search of the B\_tree pointed to by the PSET\_CAT entry for the Pset, and returns the ID of the first element in the Pset which contains a match with the key, or a null value if not found. H SEARCH performs a hash search, using the scatter table pointed to by the PSET\_CAT entry for the Pset, and the pointer slot designated in the catalogue entry to be used for overflow chaining. It uses the system HASH function to hash the key into the scatter table. If the corresponding entry in the table is not null, then it checks the contents of the BEU pointed to by

of that BEU. Otherwise, it performs a linear search of the overflow chain until it either finds a match or a null pointer slot.

If a match is found and the retrieval mode is (1) then the ID found is placed on the top of the stack and SEARCH returns. If a match is found but the mode is (2) then a linear search is used to retrieve any additional elements. If the link type is Hashed, then only the remainder of the overflow chain need be searched. If the link type is a B\_tree, then only the right descendents need be searched until a match isn't found. This is because elements having the same key are linked via the right descendent pointer slot and are, hence, chained together. However, if the link type is Linear then an exhaustive search of the remainder of the Pset is necessary.

If the retrieval mode is (3), that is, that all elements in the set be fetched then one of 3 routines is called. If the link type is Linear then LINEAR\_L is called which retrieves all the IDs in the set by simply following the pointer chain pointed to by the PSET\_CAT entry for the Pset. If the link type is B\_tree then LINEAR\_B is called which per-

forms an inorder traversal of the B-tree pointed to by the PSET\_CAT entry. Finally, if the link type is Hashed then LINEAR\_H is called. This routine goes through the scatter table pointed to by the PSET\_CAT entry for the Pset and returns all the IDs which are found either in the scatter table or in the associated overflow chains. In any event, the IDs found are placed on a stack and SEARCH returns.

#### 3.2.3.4 FETCH

This module is responsible for fetching the contents of one or more elements within a Pset, given the name of the Pset, the retrieval mode, and a key if needed. The retrieval modes are identical to those of SEARCH. The FETCH module returns a temporary database called INFO\_ND which contains the data portions of the elements fetched (See description of INFO\_ND in database section). Conceptually FETCH is very simple, because it relies on the SEARCH module to retrieve the IDs of the desired elements. The first thing FETCH does is call SEARCH, passing it the name of the Pset, retrieval mode, and key value. SEARCH returns a stack of pointers (i.e. in the temporary database ID311 which point to the BEUs containing the desired elements. FETCH then takes the top of the stack, overlays a BEU template on the memory

location specified by the ID on the top of the stack, extracts the data portion of the BEU, and places it on the top of the INFO\_ND stack. It then pops the IDS1 stack and continues until the stack is empty.

## 3.2.3.5 CREATE E

This module is responsible for creating a BEU given a bit string representation of a data value and the length of that string. It returns a pointer to the newly created BEU which serves as the BEU's ID. Basically, the module allocates a BEU, initializes the P\_array to contain null values, inserts the bit string into the data portion of the BEU, and sets the length field accordingly. It then returns the pointer which points to this allocation of the BEU.

## 3.2.3.6 CREATE I

This module is responsible for creating an allocation of the INDEX database to be used as a scatter table for a given Pset. It returns the pointer to this allocation of INDEX. It requires the name of the Pset and the length of the key to be hashed. The procedure is straightforward. It allocates a copy of INDEX, initializes the pointer array to null, inserts the name of the Pset and the length accordingly, and returns the pointer to this allocation of INDEX.

## 3.2.3.7 HASH

This function is used to hash key values, specified as bit strings, into the scatter tables used to link the Psets. It requires the key value and the length, in bytes, of the key. The hashing function is as follows: It takes the key, 2 bytes at a time, treats it as an unsigned integer and adds it to a running total for the key. Once the key has been converted in this fashion, it is divided by the size of the scatter table + 1, and the remainder represents the hashed value. Since HASH is implemented as a function, it takes on the value of the hashed value.

## 3.2.3.8 INIT\_P

This module is responsible for initializing the PSET\_CAT Pset. Hence, it must be called before any other Pets are defined. The module contains a temporary structure which is initialized to contain the desired Pset organization for the PSET\_CAT Pset. It calls CREATE\_E, passing it the information contained in the structure. The BEU that is created represents the PSET\_CAT catalogue entry for the PSET\_CAT Pset. CREATE\_I is then called to create a scatter table for the Pset, and the p\_array of the BEU is updated accordingly. The HASH function is then called, passing it PSET\_CAT as the

key, and the corresponding entry in the scatter table is
updated to point to the BEU containing the catalog entry.
Finally, the ID of the catalogue entry is saved in a static
External variable called PCATPTR. The resulting structure
for the PSET\_CAT Pset was shown in table 4 .

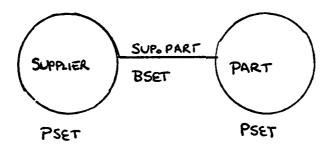

## 3.2.4 The Binary Layer

The conceptual data model of the Binary layer is the BINARY SET (Bset). A Bset is defined to be a set of relationships or associations, possessing some common meaning, between elements of 2 Primitive sets. For example, if one Primitive set consists of supplier's names, and another Primitive set consists of parts, then one could define a Binary set linking suppliers to the parts that they supply. It is a Binary relationship in the sense that only 2 sets of elements are involved, however, an instance of a Binary set in no way need be 1 to 1. For example, an instance of this Bset might consist of all the parts supplied by supplier A. In this case the relationship might be 1 to n, or even m to n if more than 1 supplier supplies the same part. A Binary association is simply an instance of a Binary set. A Binary set is considered to be uni-directional, i.e. supplier-parts is one Bset, parts -supplier is another Bset.

However, the existence of a Bset implies the existence of it's reciprocal.

Thus, a Binary set is represented by a collection of links between elements in two Primitive sets. It is typically diagrammed as shown below, where the circles or nodes represent the Primitive sets and the arc represents the Binary set linking the two Primitive sets.

Diagram of a Binary Set

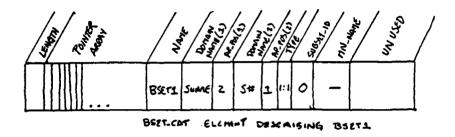

The purpose of the Binary layer is to map requests on its conceptual data model (the Bset) to it's physical representation, i.e. as links among elements of 2 Primitive sets. The Bset is implemented via the pointer slots of the BEUs which contain the associated elements in the Psets. This means that the Binary level must be aware of the structure of BEUs, be able to modify the contents of the F\_arrays of

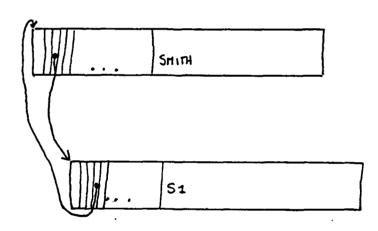

the BEUs, and be aware of the organization of the Psets (i.e. it must have access to the PSET\_CAT). In addition, the Binary layer must maintain a catalogue of all the Bsets defined in the system. This catalogue would contain for each Bset, the name of the Bset, the names of the Psets involved, specification of the type of Binary association found in the Bset, and implementation information.

The type of Binary association in the Bset determines the method by which the Bset is implemented. Table 8 illustrates the implementation of a 1 to 1 Binary association. If the type of Binary association is 1 to 1, then the Bset define module uses the information contained in the PSET\_CAT entries for the 2 Psets to locate and reserve a free pointer slot in the BEUs of each Pset to be used for Bset linkage. All Binary associations in the Bset will use the same pointer slots to implement the Binary linkage. Note also that the pointer slot need not be the same in the two Psets. Binary association is created by setting the contents of the appropriate pointer slot in the BEU containing the desired instance of the first Pset, so that it points to the BEU containing the desired instance of the second Pset, vice-versa.

TABLE 8

Implementation of a 1 to 1 Binary Association

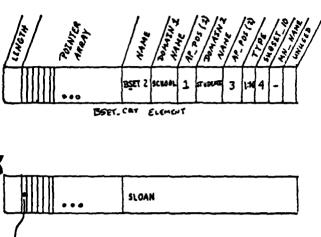

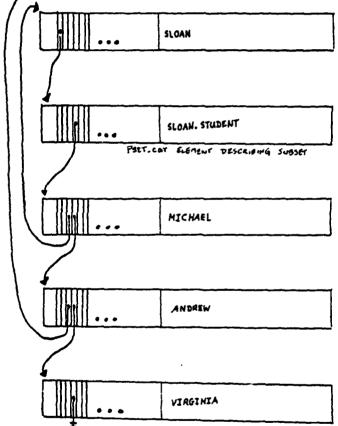

If the type of Binary association is 1 to n, then it becomes more complicated, as shown in table 9. The Bset define module still locates and reserves a free pointer slot in the BEUs of each Pset. However, the pointer slots are put to different uses. The pointer slot in an instance of domain 1 of the Binary set does not point directly to the associated instances within domain 2, but rather it points to a PSET CAT entry for a subset of domain 2. The subset is defined as being those elements in domain 2 which are related via the Binary association to that instance of domain 1. Hence, the Binary layer must request that the Pset layer create a PSET\_CAT entry for the subset. In order to retrieve an instance of the associated elements in domain2, it is necessary to follow the pointer in the instance of domain 1 to the subset catalogue entry, and then follow the pointer chain specified in the subset catalogue. The pointer slot in the associated instances of domain 2 points to the associated instance of domain 1.

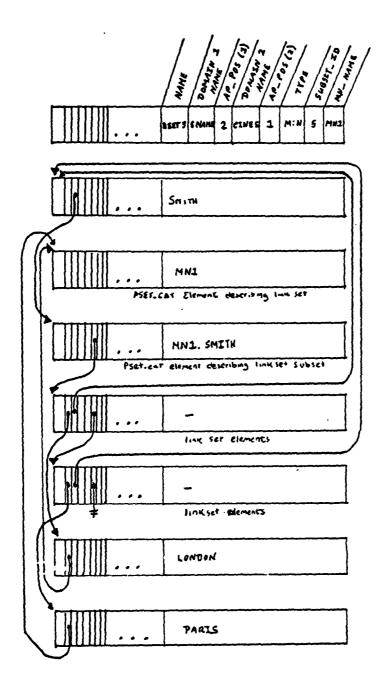

N to 1 Binary associations are implemented in an analogous fashion, except that the pointer slot in an instance of domain 1 points to the associated instance in domain 2, whereas the pointer slot in an instance of domain 2 points to a PSET\_CAT entry corresponding to a subset catalogue entry for domain 1.

TABLE 9 - Implementation of a 1 to N Binary Association

M to N Binary associations require the creation of a Primitive set which acts as a link set between instances in domain 1 and domain 2. This is illustrated in table 10. Each element in the link set links one instance of domain 1 to one instance of domain 2. Once again, the Bset define module locates and reserves a pointer slot in the BEUs of each Pset, however, they too are used for different purposes. The Bset definition module also calls the Primitive Layer to define a Pset to be used as a link set. The Binary association is implemented so that the pointer slot of an instance of domain 1 points to a PSET\_CAT entry corresponding to the subset of elements in the link set which are used to link that instance of domain 1 to it's associated elements in domain 2. By contrast, the specified pointer slot in an instance of domain 2 points to the PSET\_CAT entry for the Primary set definition of the link set. Thus to retrieve an instance of a m to n Binary association, it is first necessary to establish the instance of domain 1. must follow the pointer in the specified pointer slot of the BEU containing the instance of domain 1 to establish the subset definition within the link set. Then for each instance of the subset, the pointer contained in the appropriate pointer slot must be followed to establish the associated instances of domain 2.

Two things should be noted here. The first is that the discussion so far presumes that the instance of domain 2 exists. This need not be the case. A Pset corresponding to domain 2 must be defined prior to the definition of a Bset which involves that Pset. However, if an instance of domain 2 does not exist when a Binary association is being created, the Binary layer will call on the Primitive layer to create the required instance of domain 2. In addition, if the type is M to N the Bset layer will call on the Primitive layer to create elements within the link set. The second point is that actions on a Bset are always specified in terms of an instance of domain 1. That is, given a Bset definition, and an instance of domain 1 actions are performed on the associated instances of domain 2.

# 3.2.5 Databases of the Bset Layer

The Bset layer implements it's data model via the databases and modules of the Primitive layer together with 1 layer specific database, BSET\_CAT, and 3 layer specific modules, DEFINEB, CREATEB, SELECT. In the following sections we will the databases and modules unique to the Binary level.

## 3.2.5.1 BSET CAT

Every Binary set defined in the system has an entry in the BSET\_CAT. The BSET\_CAT entry for a Binary set provides information on the Binary set and how it is implemented. Specifically, an entry in the BSET\_CAT is declared as follows:

- 1 BSET\_CAT DEFINED(BASE)
  - 2 SET\_NAME BIT(64),
  - 2 DOMAIN INFO(2),
    - 3 NAME BIT(64),
    - 3 AP\_POS BIT(8),
  - 2 TYPE BIT(8),
  - 2 SUB\_ID BIT(8),
  - 2 MN\_NAME BIT(64),

BASE BIT(320);

Where each element is interpreted as follows:

SET\_NAME - This is the name of the BSET.

DOMAIN\_INFO(2) - For each Pset (i.e. domain) in the Bset it is necessary to know the name of the Pset, which is specified by NAME(i), and the position of the pointer slot reserved in the Pset for implementing the Binary association, which is specified by AP\_POS(i). Note, the names specified

cified are those of the Primary sets involved and not those of the subsets which may be defined during creation of a Binary association.

TYPE - This element specifies the type of Binary association found in the Binary set. The type may be either 1 to 1, 1 to n, n to 1, or m to n. A bit string code is used to represent the type of Binary association contained in the Bset.

SUB\_ID - If the type is anything other than 1 to 1, then some form of subset chaining is involved as discussed in an earlier section. This field specifies the pointer slot in the Pset which is to be used for subset chaining.

MN\_NAME - If the type is m to n, then this field is used to specify the name of the link set used to implement the Bset.

BASE -This is used to overlay the BSET\_CAT entry on the data portion of the BEU in which it is contained. The BSET\_CAT is implemented as a Pset, where each element in the Pset corresponds to a BSET\_CAT entry. Via a string overlay, the contents of a BEU containing an entry of the BSET\_CAT, can be interpreted as such. This means of implementing the

BSET\_CAT allows the Bset layer to use the functions provided by the Primitive layer to help it manage its catalogue. For example, the CREATEP module can be used to insert new entries into the BSET\_CAT, and the SEARCH and FETCH modules can be used to retrieve elements in the BSET\_CAT. This is a clear example of how the concept of a functional hierarchy can reduce redundancy of function.

# 3.2.6 Modules of the Binary Layer

#### 3.2.6.1 DEFINEB

This module is responsible for defining the physical representation of a Bset, given the name of the Bset, the names of the 2 Primary sets involved, and the type of Binary association. To accomplish this task it must: 1) check for the existence of the 2 Psets, 2) locate and reserve a free pointer slot in each Pset, 3) If the link type is anything other than 1 to 1 it must reserve an additional pointer slot in one of the Psets to be used for subset chaining, 4) If the set type is m to n it must define a Pset to act as a link set, and e) it must build the BSET\_CAT entry for the Bset and have it inserted into the BSET\_CAT Pset.

Tasks 1), 2) and 3) require that the DEFINES module have access to the PSET\_CAT entries for the Psets involved. It

calls the SEARCH module to retrieve the IDs of the needed PSET\_CAT entries, and overlays a copy of PSET\_CAT on the BEUs found, hence allowing it to interpret the contents of the BEUs as entries in the PSET\_CAT. It locates and reserves pointer slots in the same manner as the Primary layer, i.e. via calls to the MAPSET module, except that the relevant map in the catalogue entries is the AP\_MAP. Note, since the DEFINEB module is working on the the actual PSET\_CAT entries for the Psets, they are automatically updated to reflect any changes made by the DEFINEB module. DEFINEB also has an equivalent mode whereby if a Bset being defined is the reciprocal of an existing Bset, then the same pointer slots are used to implement the 2 Bsets.

Task 4) is accomplished via a call to DEFINEP, passing it the name of the link set to be defined and it's characteristics. In a similar manner, to perform task e) CREATEP is called, passing it BSET\_CAT as the name of the Pset and a bit string representation of the new BSET\_CAT entry as the data value.

#### 3.2.6.2 CREATEB

This module is responsible for implementing an instance of a Bset, given the name of the Bset, a means of establishing the instance of the first domain, and a data value to establish the instance of the second domain. In order to implement the Binary association the CREATEB module must accomplish several tasks: 1) It must first fetch the BSET\_CAT entry for the Bset, then 2) it must establish the desired instances within domain 1 and domain 2, finally 3) it must implement the linkage in accordance with the Binary association type specified in BSET CAT entry for the Bset.

Task 1) is accomplished via a call to the FETCH module, passing it BSET\_CAT as the Pset name and the name of the Bset as the key. FETCH returns a bit string which corresponds to the data prtion of the BEU which contains the catalogue entry. By setting BASE equal to this bit string, the BSET\_CAT structure is, in effect, overlaid on the bit string, and the contents of the bit string can be interpreted accordingly.

Task 2) is also straightforward. When CREATEB is called, the desired instance of domain 1 must already exist. However, it is not necessary for the instance of domain 2 to

exist. The desired instance of domain 1 can be identified in the call either by its ID or by a key value. If a key is specified, then the SEARCH module is invoked to return the ID of the element in domain 1 which matches the key. If no element is found the module returns. Since, the desired instance of domain 2 is specified via a key, it is necessary to call SEARCH to establish if the desired instance of domain 2 exists. If it doesn't, then CREATEP is called to create an instance of the element in domain 2.

Task 3) is fairly complex because of the possible need to define a subset catalogue entry. If the Binary association is 1 to 1 the linkage is straightforward. If the link type is 1 to n then the appropriate pointer slot in the BEU containing the instance of domain 1 is examined to see if it is null. If it is, then DEFINEP is called to create a PSET\_CAT definition for the subset within domain 2, and CREATEB places the ID of the catalogue entry in the pointer slot of the BEU in domain1. In either event, the instance of domain 2 is inserted into the subset specified by the subset catalogue entry. The pointer slot in the instance of domain 2 is then updated to point to the instance of domain 1. If the set type is n to 1, similar logic is employed. If the set type is m to n, then if the pointer slot in the BEU contain-

ing the instance of domain 1 is null, then DEFINEP is called to create a subset definition for a subset within the link set, and the pointer slot in the BEU is updated to point to this catalogue entry. In any event, CREATEP is called to insert a new link element into the subset, and the appropriate pointer slots in the link element are updated to point to the associated instances of domain 1 and domain 2. Finally, the pointer slot in the instance of domain 2 is updated to point to the Primary set catalogue entry for the link set.

#### 3.2.6.3 SELECTF

This module is responsible for retrieving the associated instances of domain 2, given the name of the Bset and a means of identifying an instance of domain 1. It returns the associated instances of domain 2 in the temporary database INFO\_ND. The logic is straightforward. It first calls FETCH to retrieve the BSET\_CAT entry for the Bset. If the instance of domain 1 is identified by a key value, then SEARCH is called to return the ID of the BEU containing the desired instance of domain 1. The associated elements in domain 2 are also fetched via the FETCH module. If the set type is 1 to 1 or N to 1, then FETCH is called, passing it the con-

the instance of domain 1 which represents the ID of the associated element in domain 2. If the type is 1 to N, then FETCH is called, passing it the name of the PSET\_CAT catalogue entry pointed to by the pointer slot in domain 1 as the name of the Pset to fetch, and specifying a retrieval mode of all. This has the effect of fetching all of the elements contained in the subset. If the type is m to n, a similar approach is used to retrieve the subset of link elements which link the instance of domain 1 to instances of domain 2. FETCH is then called for each element in the subset of the link set, passing it the contents of the pointer slot used in the link set to point to instances of domain 2.

# 3.2.7 Concluding Remarks on Internal Level

This concludes our discussion of the Internal level. The conceptual data model it presents to the Nset or Conceptual layer is that of Primitive sets and Binary sets. On the one hand this is a very simple data model, yet by building up aggregates of Primitive sets and Binary sets it is possible to support complex data structures. As we will see later on, the Conceptual level's data model is nothing more than the aggregation of Primitive sets and Binary sets. The power of

this approach is that while the Conceptual level makes great use of Binary and Primitive sets, it is not necessary for it to be concerned with the actual implementation of them. It simply issues calls to the Internal level to either define Primitive and Binary sets, or to insert elements into them, or to retrieve elements from within a Primitive set or that are associated through a Binary set. It is the Internal level's responsibility to translate the requests which are in term's of its conceptual data model into operations on the data model as actually implemented by the Internal level.

The hierarchical relationship of the Binary layer to the Primitive layer should have been apparent from this discussion. We have seen that the BSET\_CAT is implemented as a Pset. As a result, it is possible to make use of the functions provided by the Primitive layer to perform many of the requisite catalogue management tasks. Rather than write a specialized BSET\_CAT search routine, it is possible to use the Primitive layer's SEARCH routine. In a similar fashion, there is no need for a specialized BSET\_CAT insert routine, because the Primitive layer's CREATEP routine can be used. Even the Binary layer routines such as CREATEB rely on the Primitive layers routines. For example, if an instance of

domain 2 need be created, the CREATEB routine calls CREATEP to create the new element.

The power of this approach is that it reduces redundancy of function to a minimum, which is one of the prime objectives of the functional hierarchy concept <Madnick79>. This serves a dual purpose. On the one hand, it greatly decreases development time because once a particular functional module has been tested and debugged it can be used by any other module which needs to perform that same function. On the otherhand, it increases the reliability of the system not only because it reduces the complexity of the system, but also because it isolates functionality. That is, if a particular function is not being performed correctly, the problem can be isolated to a particular module, rather than having to change multiple modules all of which perform a similar function.

## 3.3 THE NSET LEVEL

The Nset or N-ary level sits on top of the Internal level, and beneath the External level. The role of the Nset level is to provide an interface between the External and Internal levels, and in effect shield them from each other. It allows the External level to express actions on the data-

base in terms of the Nset level's conceptual data model. The Nset level then translates these actions into the appropriate calls to the Internal level. In this manner, the External level is made completely independent of the implementation of the Internal level.

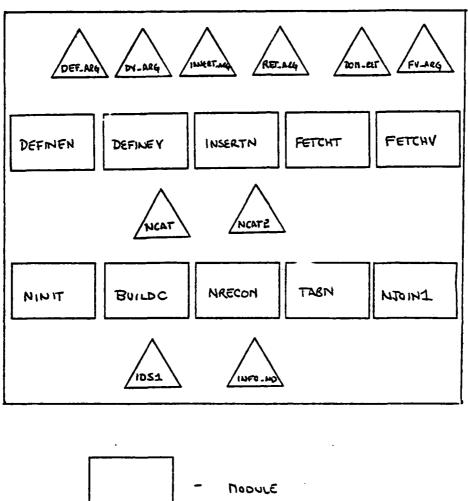

## 3.3.1 Overview of the Nset Level

This section will describe the conceptual data model of the Nset level, and outline the logical structure of the level. Table 11 illustrates the modules and databases of the Nset level.

The data model chosen for this implementation is a modified Binary network. The basic structure is referred to as an Entity set. Conceptually, an Entity set consists of one or more attributes which collectively describe an object or entity. An instance of an Entity set is represented by the collection of instances of it's attributes. Table 12 illustrates a way of diagramming an Entity set using the concept of nodes and arcs. There are 2 types of nodes in an Entity set, value nodes, which correspond to attributes, and entity nodes which act to join the attributes. An entity node derives it's value from the values of the attached value nodes. The arcs connecting the nodes represent sets of

TABLE 11

The Modules and Databases of the Nset Level

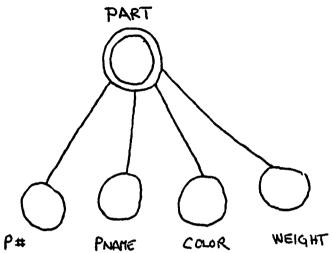

Binary associations (i.e. Binary set) connecting the attributes to the entity node.

As the reader has probably deduced an Entity set can be viewed as a collection of Primitive sets and Binary sets which have some collective meaning. The nodes represent Primitive sets and the arcs, Binary sets. More specifically, an Entity set consists of n Primitive sets which contain actual data values, linked via 2n Bsets to a Primitive set which contains no data other than information needed to link the instances of the attributes. 2n Bsets are required to implement essentially bi-directional links between the attributes and the entity node. The Binary association between an attribute and the entity node may be 1 to 1, 1 to n, n to 1 or m to n.

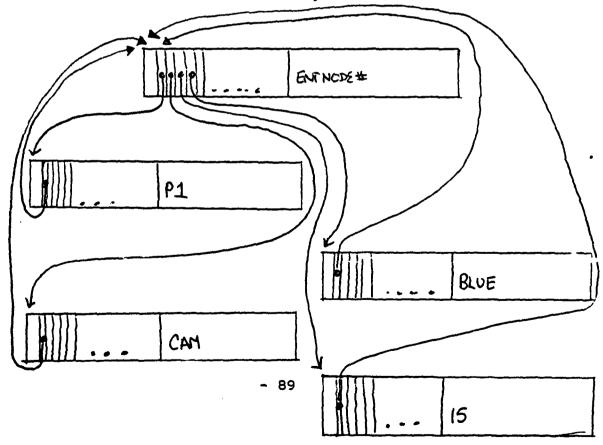

Several points are worth noting here. First, it should be clear that mapping the conceptual data model of the Entity set to the conceptual data model of the Internal level is straightforward. Second, entity sets provide a very simple mapping for the External data model of the relation. Conceptually a relation can be viewed as a special type of Entity set. The domains correspond to attributes, and a tuple corresponds to an instance of the Entity set. In addition, the

TABLE 12

Example of an Entity Set

IMPLEMENTATION OF AN INSTANCE:

Bset connecting an attribute to the entity node, is restricted to 1 to 1 (if the attribute is a unique key) or n to 1 (if a value of the attribute can be in more than one tuple) if the Entity set is used to implement a relation. A third point to note is that this structure is conceptually identical to a fully inverted file. Once an instance of a particular attribute is found, it becomes a simple matter to find all the instances of 1 or more Entity sets which have that instance of the attribute. Finally, there is at most 1 occurence of a given data item within an attribute, no matter how many Entity sets containing that attribute. Thus the problems of data redundancy largely disappear.

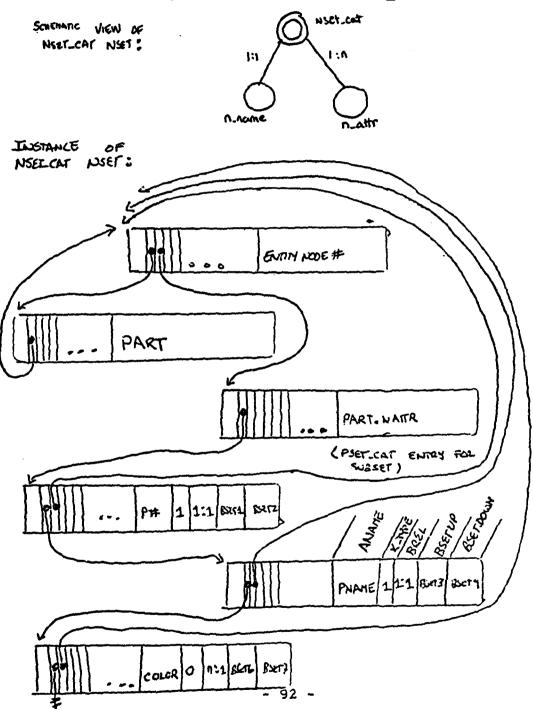

The task of the Nset level is to accept actions against its conceptual data model and map them to the necessary calls to the Internal level which would actually perform the required actions on the physical representation of the database. For example, to define an Nset, given a name, the names of the attributes and information concerning the relationship of the attributes to the entity, the Nset level must perform several tasks. First, it must have the Internal level define a Pset to act as the entity node. Then, for each attribute it must call the Internal level and have it define a Bset linking the Pset acting as the entity node to

the Pset acting as the attribute node. This presumes that the Internal level was called earlier to define the Psets referenced as attributes. Finally, it must create a catalogue entry describing the Nset, and have the Internal level insert the physical representation of the catalogue entry into the the physical representation of the Nset catalogue.

The Nset catalogue is implemented as an Nset called NSET\_CAT as shown in t. It consists of 3 Psets (N\_NAME, which contains the name of the Nset; N\_ATTR, which contains the attribute descriptions; and, NSET\_CAT which acts as the entity node) and 2 Bsets connecting the 2 attribute Psets with the entity node Pset. Since the NSET\_CAT is nothing more than an aggregation of Psets and Bset, its possible to use the Internal level's routines to help retrieve and manage the catalogue. For example, to retrieve an instance of the NSET\_CAT, the FETCH routine is called to establish the desired instance of the name attribute. The SELECTF routine is then called to establish the associated instance of the entity node. It is then called again to retrieve the associated elements of the attribute description Pset.

To insert an instance of an entity into a Nset, given the name of the Nset and values for the attributes, the first

TABLE 13
Implementation of the NSET\_CAT

entry for the Nset. The level must then check to insure that insertion of the instance of the Nset would not violate the definition of the Nset (i.e. is a unique key value already existed in the Nset). Once again, it would be the Internal level which would be called to perform the searching. Given, that it was a valid request, the Nset level would then call the Internal level to create an instance of the Pset acting as the entity node. Finally, for each attribute it would call the Internal level to create a Binary association between the instance of the entity node Primitive set and an instance of the attribute Pset containing the appropriate value.

Retrieval is somewhat more complex, in that a request may specify restrictions on certain attributes (i.e. p = 298), and may encompass more than 1 Nset which share common attributes (i.e. if a join is being requested). The External level specifies a retrieval request via a temporary structure called RET\_ARG. RET\_ARG contains: the names of the Nsets to be fetched, and any restrictions on the values of attributes including join restrictions. The first task is to build a temporary database which combines the information contained in the request, together with the NSET catalogue

entries for each Nset specified. This is accomplished in part via multiple calls to the Internal level. Restrictions other than join restrictions are then taken into account. For any attribute on which a restriction has been placed, the Internal level is called, first to locate the instance of the attribute which meets the restriction and then to locate the associated instances of the entity node for that Nset. These entity nodes are then compared to other entity nodes for the Nset which satisfied previous restrictions. The intersection of those nodes represents the entity nodes which satisfy all of the non-join restrictions specified for attributes of that Nset. Once this is done for all of the Nset's specified in the request, the join restrictions are followed through. This is done by going through the set of restricted entity nodes for one of the Nsets and for each node establishing the entity nodes in the other restricted sets of entity nodes which both satisfy the join criteria for this Nset as well as with other Nsets specified in the request. The complicating factor here is that a retrieval request can specify joins on more than 2 Nsets, the reason for which will be discussed in reference to the External level. The result of the join operation is a collection of entity nodes which satisfy all of th restrictions specified

ALFRED P SLOAN SCHOOL OF MANAGEMENT CAMBRIDGE MA CEN--ETC F/6 9/2 INFOSAM: A SAMPLE DATABASE MANAGEMENT SYSTEM.(U) AD-A116 593 DEC 81 B BLUMBERG CISR-M010-8112-07 N00039-81-C-0663 UNCLASSIFIED NL **2** of 4 40.4 116593

in the request. The entity nodes are then organized to form a table, where the rows correspond to instances of joined Nsets and the columns correspond to the different Nsets involved. This structure acts as a proxy for the relation satisfying the join and select restrictions specified in the retrieval request. The final task is to fetch the associated instances of the attributes. The retrieved values for the attributes are placed in a temporary database which is returned to the External level.

The reader should note that joins are conceptual rather than physical. When a join is specified by the External level, it is done so within the context of a retrieval request, rather than within the context of a define request. That is, a new Nset is not created, at the Nset level, as a result of a join action. However, the user sees an implicit Nset which is consistent with the join action. This means that every time a user wants to see the contents of the Nset 'created' by the join action, the Nset level must go through the join logic described above. This may be inefficient if it is referenced a great deal.

## 3.3.2 Databases of the Nset Level

The Nset level has 3 classes of databases which it uses to implement its data model and communicate with the other layers. The first type is the NSET CAT which the Nset level maintains to implement it's data model. It provides information on all of the Nsets defined in the system. The second type of Databases are those which are used by the Nset and External levels to communicate with each other. INSERT\_ARG, RET\_ARG, DV\_ARG, DEFINE\_ARG are all used by the External level to provide information to the Nset level neccessary to implement requests made by the External level. DOM RET is used by the Nset level to return data values, resulting from a retrieval request, back to the External level. The third type are databases used to communicate with the Internal level, i.e. INFO ND and IDS1, both of which were discussed with regard to the Internal level and so will not be discussed here. In the following section we will outline the structure of the databases mentioned above.

# 3.3.2.1 NSET\_CAT

This database is used to manage the implementation of the Nset level's data model. Every Nset defined in the system has an entry in the NSET\_CAT which describes the Nset and

provides information on its implementation. The NSET\_CAT is viewed by the Nset level as being an Nset and is implemented as shown in Table 13 Since, an entry of the NSET\_CAT is ultimately stored as a collection of BEUs, all of the fields are specified as bit strings. Whenever an entry of the NSET\_CAT is required, the BUILDC module maps the NSET\_CAT entry into the following data structure:

- 1 NCAT,
  - 2 NNAME BIT(64),
  - 2 NATTR BIT(8),
  - 2 ATTR(20),
  - 3 ANAME BIT(64),
  - ( 3 K\_TYPE,
    - 3 BREL ) BIT(8),
  - ( 3 BSETUP,
    - 3 BSETDOWN ) BIT(64);

Where each element is interpreted as follows:

NNAME - A unique name identifying the Nset.

NATTR - Number of Attributes in this Nset.

ATTR(20) - For each attribute in the Nset:

ANAME - Name of a previously defined Primary set.

K\_TYPE - Used to specify if instances of this attribute uniquely define instances of the Nset, i.e. if this is a key or candidate key.

BREL - The type of Binary association between instances of the entity node and instances of the attribute. In this implementation the type is limited to 1 to 1 (if instances of the attribute uniquely define an instance of the Nset), or n to 1.

BSETUP - Name of the Bset used to implement the attribute-entity Binary association.

BSETDOWN - Name of the Bset used to implement the entity-attribute Binary association.

There is an associated database called NCAT2 which is created during the retrieval process. It is implemented as an array where each element corresponds to the NSET\_CAT entry for an Nset and retrieval information for that Nset derived from the RET\_ARG database. There is an element for each Nset specified in the retrieval request. This database is declared as follows:

- 1 NCAT2(5),
  - 2 NCAT INFO LIKE NCAT,
    - 3 RET\_INFO,

- (4 FETCH,
- 4 SAME ) BIT(8),
- 4 VALUE BIT(160);

Where the RET INFO fields are interpreted as follows:

FETCH - Used to specify if values of the attribute are to be fetched. This allows the retrieval request to essentially project the Nset on desired attributes.

SAME - Used to specify if the attribute is the same as an attribute in another Nset specified in the request. The first 4 bits of SAME specify the index of the Nset in NCAT2, the last 4 bits specify the index of the attribute within the Nset. (SAME is described in greater detail in a later section)

VALUE - Used to specify any restrictions placed on the attribute in the retrieval request. As currently implemented, only equality restrictions are supported.

#### 3.3.2.2 Inter-level Communication Databases

The databases described in this section are temporary databases used by the External and Nset levels to communicate with each other. They are temporary in the sense that they are not stored as Psets and Bsets, and, in fact, exist only while certain routines are active.

# 3.3.2.3 DEF\_ARG

Used in conjunction with a DEFINEN request (i.e. a request by the External level to define an Nset). Specifies the conceptual structure of the Nset to be defined. It is declared as follows:

- 1 DEF\_ARG,
  - 2 NNAME BIT(64),
  - 2 NATTR BIT(8),
  - 2 ATTR(20),
    - 3 ANAME BIT(64),
    - 3 K\_TYPE BIT(8);

Where each element has the following meaning:

NNAME - Unique name identifying Nset to be defined. Entity node Pset takes on this name.

NATTR - The number of attributes in this Nset.

ATTR(20) - The following information must be specified for each attribute:

ANAME - Name of attribute. Must uniquely identify a previously defined Pset.

K\_TYPE - Specifies if values for this attribute uniquely define the instance of the Nset.

### 3.3.2.4 DV ARG

Used by the External level in conjunction with a DEFINEV call to specify the structure of a value node(i.e. a Primitive set) to be defined by the Nset level. It is declared as follows:

- 1 DV ARG
  - 2 NAME BIT(64),
  - 2 KEY\_LEN BIT(8);

Where each element is defined as follows:

NAME - Unique name of the Value node to be defined. The Primitive set defined by the Nset level a result of this request takes on this name.

KEY\_LEN - Length of key field within value node/Pset. Specified in terms of bit length.

#### 3.3.2.5 INSERT ARG

Used by External level in conjunction with an INSERTN call to specify a tuple to be inserted by the Nset level into a previously defined Nset. It is declared as follows:

- 1 INSERT\_ARG,
  - 2 NNAME BIT(64),
  - 2 NATTR BIT(8),
  - 2 ATTR(20),

- 3 NAME BIT(64),
- 3 VALUE BIT(320);

Where the elements are interpreted as follows:

NNAME - Name of previously defined Nset into which this instance is to be inserted.

NATTR - Number of attribute-values specified in this request.

ATTR(20) - The following information must be supplied for each instance of an attribute specified in the request:

NAME - Name of attribute. Note, the order in which attributes are specified is not important.

VALUE - Bit string representation of instance of attribute.

## 3.3.2.6 RET\_ARG

Used by External level to specify arguments of a retrieval request to the Nset level. It allows the External level to specify the equivalent of a join on up to 5 Nsets, place restrictions on the values of attributes, and specify which attributes are to be fetched. It is declared as follows:

1 RET ARG,

- 2 NUMN BIT(8),
- 2 NSET(5) BIT(64),
- 2 ARGS(20),
  - 3 N\_INDEX BIT(8),
  - 3 NAME BIT(64),
  - 3 RET INFO,
    - (4 FETCH,
      - 4 SAME ) BIT(8),
      - 4 VALUE BIT(160);

Where each field is defined as follows (Note, Table 14 illustrates an example of how RET\_ARG may be used to express a retrieval request, and the reader may want to study that table in conjunction with the following discussion.)

NUMN - Number of Nsets specified in the request.

NSET(5) - An array used to specify the names of the Nsets involved in the request.

ARGS(20) - Every attribute of an Nset specified in NSET must have an entry in the ARG array.

N\_INDFX - Used to specify for which Nset in NSET this is an attribute description.

NAME - the name of the attribute, must correspond to an attribute in the NSET(N\_INDEX) Nset.

RET\_INFO - Used to specify retrieval information for the attribute. It contains the following elements:

FETCH - Flag to indicate if instances of this attribute are to be fetched, i.e. returned to the External level, if they are contained in instances of the Nset which satisfy all restrict and join criteria.

SAME - Used to specify if this attribute is the same as a previously specified attribute. Used essentially to specify joins. First 4 bits represent the index of the Nset, the last 4 bits specify the attribute within that Nset on which instances of this attribute are to be joined. For example, in Table 14 the Nset SP is joined on S with SUPPLIER. The SAME field for the S attribute of SP is 14 (hex) which indicates that it is to be joined with the first Nset specified in RET\_ARG, on the 4th attribute specified for that Nset. Note, this approach limits the number of Nsetsspecified in a request to 16, with a maximum of 1b attributes per Nset.

VALUE - Used to specify a value on which this attribute is to be restricted.

## 3.3.2.7 DOM\_RET

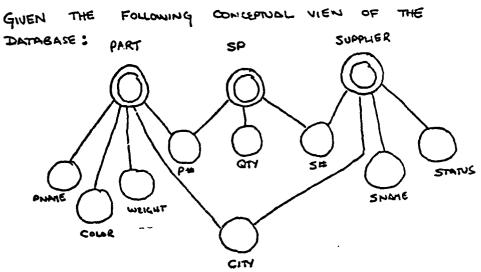

This database is used by the Nset level to return data elements to the External level retrieved as a result of a retrieval request. The database is implemented as a stack of bit strings, where each element corresponds to an instance of an attribute which met the retrieval criteria specified in RET\_ARG. Retrieved elements are placed on the stack such that instances of tuples are represented by consecutive data elements. The database is declared as follows:

- 1 DOM\_RET EXTERNAL CONTROLLED,
  - 2 D ID BIT(8),
  - 2 VALUE BIT(320);

Where each field is interpreted as follows:

D\_ID - Identifies the Nset and Attribute to which this data element belongs. Uses the same convention as used in RET\_ARG.SAME, ie. the first 4 bits specify the index of the Nset in RET\_ARG.NSET, and the last 4 bits specify the attribute within that Nset.

TABLE 14
Example use of RET\_ARG

AND THE FOLLOWING SEQUENCE OF COMMANDS:

SELECT SUPPLIER ON CITY=LONDON, S#=54 GIVING TI JOIN TI AND SP ON S# GIVING TZ PROJECT TZ ON SNAME, P#, QTY GIVING T3 PRINT T3

THE FOLLOWING COPY OF RETLAND WOULD BE PASSED TO PETLIT

HUMH	NSET	H_INDEX	NAME	FETCH	SAME	VALUE
2	SUPPLIER	1	SPAGE	1 18	1004	
	SP	1	2VIATE	1018	100H	-
	<b>-</b> .	1	CITY	10'8	Oón	"LONDON"
	-	1	S#	10'B	<b>`</b> 0 0#	`51'
	-	2	<b>5</b> #	10'8	~14'H	-
•		2	ρ#	12'8	الم′دب	_
		2	QTY	1'8	10 OH	
				<del> </del>		
			•	+-		
				+		
		<u></u>	L		لــــــا	<u> </u>

- 106 -

The second second

VALUE - Bit string respresentation of the value of this instance of the attribute.

### 3.3.2.8 The FV\_ARG database

This database is used by the External level to specify the retrieval of an instance of a Pset. It is also used by the Nset level to return either the data item or a flag indicating that no data value was found matching the key. It is used in conjunction with a call to the FETCHV module. It is declared as follows:

- 1 FV\_ARG,
  - 2 D NAME BIT(64),
  - 2 KEY VAL BIT(160),
  - 2 FOUND BIT(1),
  - 2 DATA BIT(320);

Where the elements of the database are defined as follows:

D\_NAME - The name of the domain/Pset in which to search.

KEY\_VAL - Specifies a key value on which to search.

FOUND - Specifies if an instance of the Pset was found which matched the key.

DATA - The data value found.

## 3.3.3 Modules of the Nset Level

The Nset level is implemented via 5 major modules and 5 support modules. The 5 major modules correspond to the 5 types of requests that the External level can make of the Nset level. The purpose of these modules is to translate those requests into requests to the Internal level necessary to physically implement them. In addition, they are responsible for translating the responses of the Internal level into appropriate responses to the External level. Finally, the modules are responsible for Nset catalogue maintainance where appropriate. The support modules are not callable by the External level and are used solely by the Nset modules. This section will briefly describe the modules of the Nset level.

### 3.3.3.1 DEFINEN

This procedure accepts requests to define Nsets, issues the calls necessary to implement the Nset at the Internal level, and creates a NSET\_CAT entry describing the Nset and it's implementation. It relies on information provided in DEF\_ARG to define the Nset. It begins by defining a Pset to act as the entity node for the Nset. This is done via a call to DEFINEP passing it the name of the Nset as the name of

the Pset defined. Then, for each attribute defined in DEF\_ARG it defines 2 Bsets linking the attribute to the entity node. The Bsets correspond to the entity-attribute link and the attribute-entity link. The type of Bset implemented depends on the key type specified for the attribute in DEF ARG. The Bsets are defined via 2 calls to DEFINEB, one of which specifies the equiv option so that the Bsets share the same pointer slots. Finally, the DEFINEN module creates an NSET\_CAT entry for the Nset being defined and has it inserted into the NSET CAT Nset. This is done via a call to INSERTN, passing it a copy of INSERT ARG built by DEFINEN so that it contains an entry of NSET\_CAT in a form that can be inserted into the NSET CAT Nset. Note, DEFINEN presumes that the names of the attributes reference previously defined Psets. It is the responsibility of the External level to insure that this is the case.

### 3.3.3.2 DEFINEV

This procedure accepts requests to define value nodes, issued by the External level, and issues the call necessary to create a Pset definition for the value node. DV\_ARG provides it with the name and the key length of the value set to be defined. DEFINEV is very simple. All it does is issue

a call to DEFINEP, passing it the information provided in DV\_ARG together with system default characteristics for the structure of Psets. The system default information specifies things like, link type (Hashed), maximum length (40 char), position of the key field, etc... The rationale for DEFINEV acting as an intermediary between the External and the Internal level is to entirely shield the External level from any knowledge of the Internal level.

### 3.3.3.3 INSERTN

This module accepts requests to insert instances of an Nset into a previously defined Nset, validates the request, and issues the appropriate commands to the Internal level in order to physically implement the request. It relies on INSERT\_ARG to specify the instance of the Nset to be inserted, and on the NSET\_CAT entry for the Nset to provide it with the necessary information to implement the request. The logic of the module is as follows. The module first calls BUILDC, passing it the name of the Nset, which returns a copy of the NSET\_CAT entry for the Nset. It then validates the request by checking to see that no duplicate values are specified for attributes which are defined as key attributes. Once the request has been validated, a unique tag for

the entity node is generated via a call to NAMEGEN, and CREATEP is called passing it the name of the entity node as the Pset, and the tag value as the bit string. This creates an instance of the entity Pset to be used to chain the instances of the attributes. Then, for each attribute specified, CREATEB is called to create a Binary association between the instance of the entity Pset and the attribute. CREATEB is passed BSETDOWN (from the NSET\_CAT entry) as the BSET, the Tag value as the desired instance of the entity Pset, and the attribute value specified in INSERT\_ARG as the desired instance of the attribute Pset. It is the responsibility of the CREATEB module to create an instance of the attribute Pset, if necessary.

### 3.3.3.4 FETCHT

This module accepts requests to retrieve instances of 1 or more Nsets from the database, takes into account any restrictions placed on instances of the attributes, issues the appropriate commands to the Internal level to retrieve the data values, and formats the retrieved instances into the data model of the External level. The retrieval request as specified in RET\_ARG may involve several Nsets, restrictions on all attributes, and involve joins between the vari-

ous Nsets. The resulting complexity means that FETCHT and its associated support routines NJOIN1, NRECON, and TABN represent, perhaps, the most complicated part of the system. As a result, we have provided flowcharts in tables 15 and 16 which outline the logical structure of the 2 most complicated modules, namely FETCHT and NJOIN1. The reader is urged to study those flowcharts as well as the documentation provided in appendix 2. In the discussion that follows we will discuss only the broad outlines of the modules.

FETCHT is the central module in the retrieval system. It's Primary tasks are to 1) create a database which combines the information contained in RET\_ARG and the NSET\_CAT entries for the Nsets specified in the request, 2) Oversee the restriction phase of the retrieval, 3) call Njoinl if joins are specified in the request, 4) call TABN to convert the retrieved instances of the Nsets into tabular form, and e) build and fill the database used to return retrieved elements to the External level.

Task 1) is accomplished via multiple calls to the BUILDC module. Each Nset specified in the request requires a call to BUILDC to retrieve its NSET\_CAT entry. The information contained in the NSET\_CAT entry is combined with the

TABLE 14

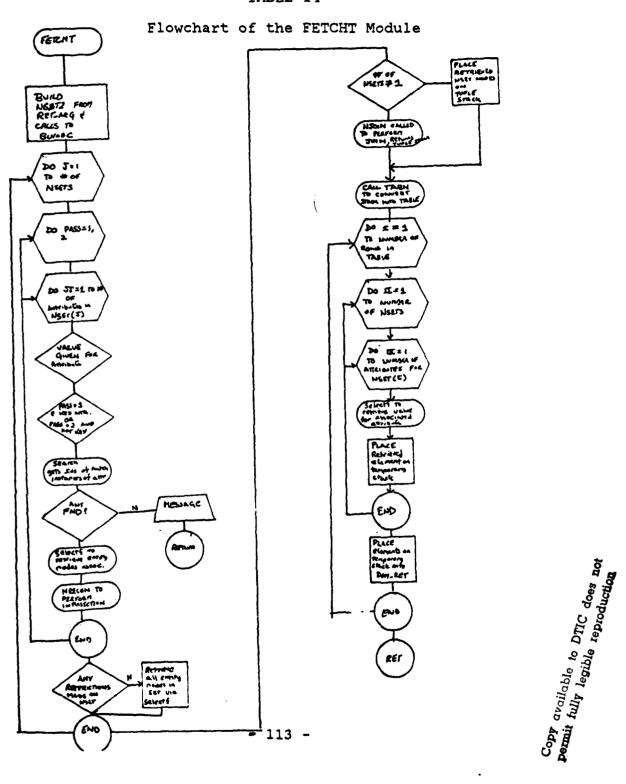

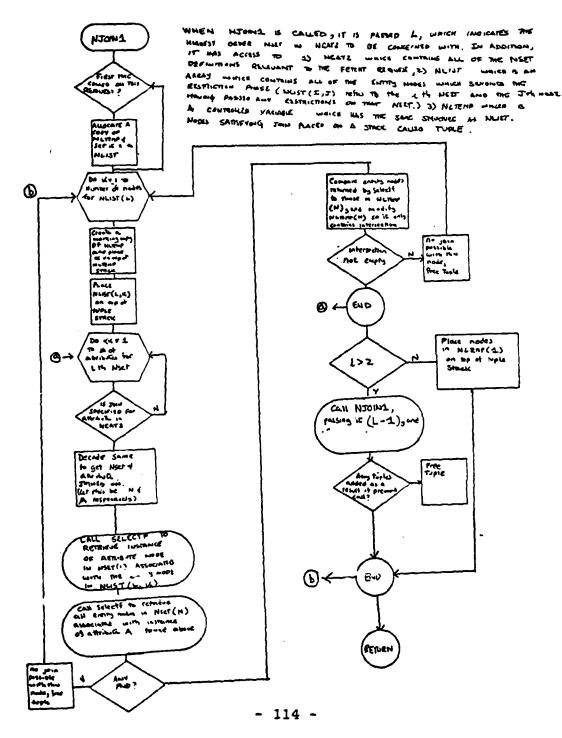

TABLE 15
Flowchart of NJOIN1 module

Copy available to DTIC does not permit fully legible reproductions

RET\_INFO information specified in RET\_ARG to form a temporary database called NCAT2. The objective here is to create one database which contains both the retrieval information (i.e. restrictions on the attributes, join information etc...) and information on how the Nset is implemented.

The objective of task 2) is to create a set of entity nodes for each Nset which satisfy any non-join restrictions placed on their attributes. This is done in two passes. On the first pass the Nset is restricted on any attributes for which a value has been specified, and which has been defined as being a key attribute. On the The rationale for doing this restriction first is twofold. First, it is the most limiting restriction placed on the Nsets (i.e. if it is key attribute, any given value of that attribute can be associated with only one instance of the Nset). This then greatly reduces the universe of entity nodes that need be considered in the second pass or during the join process. Second, since the key attribute is likely to be hashed, access is very quick. On the second pass, any non-join restrictions not taken into account on passl, are taken into account. A temporary database called NLIST is maintained which contains only those entity nodes which satisfy all non-join restrictions placed on them. The NRECON module is responsible for

maintaining that database given candidate entity nodes retrieved by FETCHT. At the end of this process NLIST contains only those instances of the Nset nodes which satisfied all restrictions placed on them.

Task 3) is performed largely by NJOIN1. The task of NJOIN1 is to create an ordered stack which corresponds to instances of the entity nodes which meet both join and all other attribute restrictions. It uses the entity nodes contained in NLIST as its universe of possible candidates. logic employed is shown in the flowchart for NJOIN1. complicating factor in NJOIN1 is that more than 2 Nsets may be involved. For example, suppose three Nsets are specified in the request, and Nset2 is joined on Nset1 and Nset3 is joined on Nset2. Hence, Nset3 is implicitly joined on Nset1 as well. To establish an instance of the joined Nsets, given an instance of Nset3, it is first necessary to establish the instances of Nset2 which satisfy the join restrictions placed on Nset3. Given those instances of Nset2 it is then necessary to restrict them to only those which satisfy join restrictions on Nsetl. At the conclusion of this process a given instance of Nset3 may be joined with X instances of Nset2 which in turn may be joined with Y instances of Nset1. This process must be repeated for each instance of the last

Nset. Since this is a recursive process, NJOIN1 was implemented as a recursive procedure. It requires that all joins be specified as joins on previously specified Nsets in NCAT2. The rationale for performing the join logic after the other restrict logic was to limit the number of entity nodes to be examined. At the end of this process the stack created by NJOIN1 would contain only those entity nodes which met all join and other restrictions specified in the request.

Task 4) is to convert the stack into a rectangular table format, where each entry in the table corresponds to an instance of an entity node. This is done essentially to convert the format of the data from the Nset data model to that of the External data model. For example in our earlier example, 1 instance of Nset 3 was joined on X instances of Nset 2, and through those instances of Nset 2 on Y instances of Nset 1. The task of TABN is to convert those entries on the stack into X\*Y tuples. It does this as follows, fills the first column in a temporary table called TAB with the elements from the stack until the tuple id is no longer 1. It then fills column 2 with the next element on the stack until column 2 contains as many elements as column 1. It then gets the next element from the stack. If its tuple id indicates that it corresponds to a 3rd Nset then the same

process as given for column2 is repeated. Otherwise, the procedure returns to column 1 and repeats the process again, starting where it left off.

The final task is to convert the table created by TABN into instances of the associated attributes, and place them in a database called DOM\_RET which is passed back to the External level. This is done by processing the table created by TABN, a row at a time, and for each entry fetching the associated attributes. Only those attributes for which the FETCH flag in RET\_INFO is turned on and which are not the same as previously specified attributes are fetched.

### 3.3.3.5 FETCHV

This module allows the External level to retrieve a single instance of a value set, i.e. a Primitive set. The External level specifies the name of the value set/Pset, as well as a key value on which to search in the FV\_ARG database. FETCHV simply calls the FETCH module, passing it the name of the Pset and the key. When the FETCH module returns, FETCHV updates the FV\_ARG database accordingly and returns. The rationale for the FETCHV module is identical to that as for the DEFINEV module.

## 3.3.3.6 BUILDC

This is a support module which is called by the other modules in order to retrieve an entry contained in the NSET\_CAT Nset and formats it into the form of the NCAT structure described earlier. It is passed the name of the NSET\_CAT entry to be fetched and a copy of NCAT. It returns the copy of NCAT containing the information contained in the NSET CAT entry for the Nset. The logic is as follows: It first fetchs the instance of the Nset name from the Pset NSETNAME via a call to FETCH. This retrieves a bit string which contains the Nset's name and number of attributes. This instance is used in a call to SELECTF to establish the associated instance of the entity node of the NSET CAT entry. Once the instnace of the entity node is fetched, it in turn is used in a call to SELECTF to retrieve the associated instances of the attribute descriptions contained in N\_ATTR. The attribute descriptions are placed into the NCAT structure via string overlays.

### 3.3.3.7 NINIT

This procedure is required to initialize the NSET\_CAT and must be called prior to any Nset definitions. It begins by issuing 3 DEFINEP calls to set up the Pset's used to imple-

ment the catalogue, NSETNAME which contains instances of the Nset names, NSETCAT which acts as the entity Pset, and N\_ATTR which is used to hold attribute descriptions. It then calls DEFINEB to set up the Bsets linking the 2 value Psets with the entity Pset. Finally it inserts the first NSET\_CAT entry into the NSET\_CAT, namely the NSET\_CAT entry describing the NSET\_CAT NSET.

### 3.4 SUMMARY OF THE NSET LEVEL

This concludes our discussion of the Nset or Conceptual level of INFOSAM. Several points are worth noting in summary. First, the Nset level effectively shields the External level from the Internal level, while at the same time making extensive use of the functions provided at the Internal level to implement the physical representation of the External data model. Second, the functionality of the Nset level is such that the External level, which implements a relational data model essentially becomes an interface between the user and the Conceptual level. As we will see in our discussion of the External level, much of the work of the External level is to create the required communication databases based on requests from the user. Third, we chose to implement a very simple form of the Nset data model. This

implementation highlights 2 points associated with that. The first is that despite it's simplicity it provides a powerful data model for the External level. The second is that despite its simplicity, its implementation is far from trivial, particularly in the area of retrieval. An Nset level as envisioned by Hsu<Hsu>, which is far more general than the one implemented here, would be a challenging task indeed.

### 3.5 THE EXTERNAL LEVEL

The External level is the highest level in INFOSAM, and as such, sits between the user and the Nset level. This is somewhat different from the structure envisioned by Madnick <Madnick79>. In his original design there were several levels between the External level and the Nset or N-ary level, for example, a data validity level and a virtual information level.Conceptually, INFOSAM could incorporate those levels, however, in this implementation we did not implement them. The External level is designed to provide the user with a simple interactive Relational interface to the system. It allows the user to define his database in terms of the relational data model, and it supports relational operations or queries against the database so defined. The External level accomplishes this by mapping the user's view, i.e. a rela-

tional view, to the conceptual data model of the Nset level, and then by issuing the calls to the Nset level necessary to implement his view at the Nset level. As a result, the user is effectively shielded from both the conceptual and physical implementation of his database.

## 3.5.1 Logical Overview of External Level

The conceptual data model of the External level and, hence the data model visible to the user, is that of domains, relations, and views. Since, the concept of domains and relations are probably familiar to the reader, they will not be discussed here. The concept of a view, however, may not be so familar. A view is defined here as the collection of relations that a given user sees or to which <Date, Hsu > A user may only issue relahe has access. tional operators (i.e. join, project, select, load and print) against relations which are within, or derived from his view. Each view has a unique ID which the user must specify before he can access relations within that view. Note, a relation can appear in more than 1 view. Thus, the concept of a view provides a measure of security control.

In order to implement actions expressed in terms of the relational data model, the External level must map those

actions to equivalent actions on the Nset representation of the relation, and call the appropriate Nset level routines. This mapping process is very straightforward, because as mentioned earlier, a relation can be viewed as a restricted form of an Nset. The domains of the relation correspond to value nodes, the relation to the Entity set, and a tuple to an instance of an Nset. Thus, a relation can be easily implemented as an Nset. When a user wishs to define a relation, the External level translates that request into a call to DEFINEN, passing it the name of the relation as the name of the Nset being defined, and the names of the domains as the associated attributes. An insertion into an existing relation is translated into an INSERTN request, passing it the name of the corresponding Nset, and the values for the attributes.

Relational operations such as joins, projects and selects are also easily mapped onto operations on the Nset model. Conceptually, a SELECT can be viewed as a retrieval operation on an Nset where instances of the Nset are restricted on the value of some attribute. A PROJECT is a retrieval request where all instances of an Nset are to be fetched but only the values for certain attributes are to be displayed. Finally, a JOIN operation is a retrieval request where the

request spans 2 or more Nsets which share 1 or more common attributes. Here, it is also necessary to normalize the returned instances to reflect the rectangular structure of the relational model. For example, at the Nset level 1 instance of Nset2 may be joined with 3 instances of Nset1, at the External level this represents 3 tuples of the relation created via the join. Conceptually then, each relational operation could be implemented by issuing a call to FETCHT, and passing it a copy of RET\_ARG which contained the necessary retrieval information.

In fact, the implementation of RET\_ARG and FETCHT is such that it allows the External level to implement the concept of virtual commands with regard to relational operations (see<Astrahan76> for a discussion of a similar approach). When a user specifies the view he wishes to use, a temporary data structure is created which is essentially an array where each element in the array is equivalent to a copy of RET\_ARG. For each relation in his view, an element in the temporary structure is set up so that it is identical to the copy of RET\_ARG required to fetch the Nset representation of the relation when a user issues a relational operation on a relation in his view, the appropriate entry in the temporary structure is updated to reflect the implications of his

request. If a user defines a temporary relation as the result of relational operations on other relations in his view, a new entry is created in the structure, such that if it were passed to FETCHT, FETCHT would retrieve the appropriate elements given the restrictions specified. The Nset level isn't called on to retrieve data until the user issues a PRINT command, hence, the notion of virtual commands. When a user specifies a relational operation, it is as if the operation was really performed, but in fact only a virtual version of the operation is performed.

The rationale for this approach is severalfold. From a user's viewpoint it gives the appearance of a faster response time since the actual consequences of a relational operation can be put off until the last possible moment. In fact, the real response time may be faster, since the sequence of operations may be such that relatively few data items ultimately need to be fetched. From a system standpoint it is also advantageous since it reduces the number of calls to the Nset level, it eliminates the need to manage the data returned as a result of an operation which is part of a sequence of operations, and the need for modules at the External level to handle relational operations on the data returned as the result of prior relational operations. If

the system were multi-threaded, there would be an additional advantage. If data were retrieved after each operation, the Nset's involved would have to be locked at the time the user accessed his view, since they might be modified between one request and the next. In this approach the Nset's would only have to be locked while the FETCHT module was being called on to retrieve the actual data items.

Since the External level acts as an interface to the User, a certain degree of attention was paid to the quality of the interface. In particular, the user interface was designed to be 'user friendly' yet able to adapt to the increased sophistication of the user as he becomes more familar with the system. Thus, the routines were set up so that a user can specify all or part of a command and be prompted for the rest. For example, a new user may need to be prompted for each item in a command, while a sophisticated user doesn't need the prompts, and in fact would probably find them a hinderance. If a user makes an error, ranging from a syntax error to a data error (i.e. enters a character where a number is required), the routines are set up so that only the offending element need be re-entered. The routines are also responsible for checking the validity of requests. For example, that relations are only defined over previously defined domains, or that views contain only previously defined relations, or that the user doesn't issue a request to define a domain, relation or view which is previously defined. As mentioned earlier, it also performs simple data validity checks. When a domain is defined, it's characteristics (type, length, minimum and maximum value if a number) must also be specified. During data entry, data being entered is checked against the characteristics specified for the domain. If it doesn't agree, an error message is printed out and the data value must be re-entered. A sample terminal session is provided in appendix I.

## 3.5.2 Databases of the External Level

The External level makes use of 3 types of databases. The first type of database represents the catalogues used by the External level to store information regarding domains, relations and views defined by the user. These catalogues are called DTABLE, RTABLE and VTABLE respectively Just as the Internal and Nset levels' catalogues were viewed as being implemented within the context of the level's data model, so too the External level views it's catalogues as relations. DTABLE is viewed as a relation containing 2 domains; DNAME, which contains the names of all domains defined by the user

and. DATTR which contains the attributes of the domains. RTABLE is also viewed as a relation containing 2 domains; RNAME, which contains the names of all the relations defined by the user, and DNAME which is the same as DNAME in DTABLE. VTABLE also contains 2 domains, one of which is also shared with RTABLE; RNAME as defined before, and V ID which contains the IDs of all views identified in the system. These relations are implemented as Nsets via a calls to the Nset level. This is illustrated in Table 17 The External level maintains and manipulates these relations using the same operators it uses to implement user defined relations. For example, when a user issues a GETVIEW command (which retrieves the names of all relations associated with a given view) the External level SELECTs VTABLE on V ID = ID as specified by user, JOINS the resulting relation with RTABLE on the RNAME domain, and projects the resulting relation on RNAME, and V ID. Note that this is all done via 1 call to the Nset level.

### 3.5.2.1 VTABLE

A tuple within DTABLE is declared as follows:

- 1 DTABLE,
  - 2 DNAME bit(64),
  - 2 DATTR,

TABLE 17

:	:
l	

- 3 TYPE BIT(8),
- 3 TLEN BIT(16),
- 3 TMIN BIT(16),
- 3 TMAX BIT(16);

Where the fields are defined as follows:

DNAME - The name of the Domain

DATTR - Contains a bit string which contains the following attributes for the domain:

TYPE - Specifies if the data type is numeric or character.

TLEN - Specifies the maximum length for a data element in this domain.

TMIN - If the type is numeric this field contains the minimum permissable value for an element of this domain.

TMAX - If the type is numeric, then this element contains the maximum permissable value. DTABLE is implemented as an Nset consisting of 2 attributes, DNAME and DATTR.

### 3.5.2.2 RTABLE

A tuple within RTABLE is declared as follows:

- 1 RTABLE,
  - 2 DNAME BIT(64),
  - 2 RNAME BIT(64);

The meaning of the fields should be clear. Note, however, that a relation of n domains requires n tuples in RTABLE. RTABLE is implemented as an Nset consisting of 2 attributes, DNAME and RNAME.

### 3.5.2.3 VTABLE

A tuple in VTABLE is declared as follows:

- 1 VTABLE,
  - 2 RNAME BIT(64),
  - 2 V\_ID BIT(64);

The meaning of the fields should also be clear. Note, too, that a view which contains n relations requires n tuples in VTABLE. VTABLE is implemented as an Nset consisting of 2 attributes, RNAME and V ID.

## 3.5.2.4 The Tl\_ARG Database

T1\_ARG represents the second type of database used by the External level. It is the temporary database through which

the External level implements its virtual relational operations. It is declared as follows:

1 T1\_ARG(20) EXTERNAL,
2 N1 BIT(8),
2 C1(5) BIT(64),
2 T2(20),
3 N2 BIT(8),
3 C2 BIT(64),
3 T3,
4 N3 BIT(8),
4 N4 BIT(8),
4 C3 BIT(160);

Which is functionally equivalent to :

- 1 T1\_ARG(20) EXTERNAL,
  - 2 VIRT\_REL LIKE RET\_ARG;

When the GETVIEW command is issued, the GETVIEW module via the logic described earlier, fetchs the RTABLE tuples for the relations specified in the user's view and loads T1\_ARG. At that point T1\_ARG will contain 1 entry per relation, and the entry can be used in the FETCHT call to retrieve a relation. As a user issues relational operations, the modules

entries in T1\_ARG to reflect the operations. If the user defines a temporary relation as the result of a relational operation on 1 or more previously defined relations in T1\_ARG, a new entry is created in T1\_ARG which reflects both the implications of the relational operation, as well as any previous operations on the relations. When the PRINT command is issued, the PRINT module finds the appropriate entry for the relation in T1\_ARG, and calls FETCHT passing it a copy of the entry. T1\_ARG is overwritten whenever a new GETVIEW command is issued, and is lost in any event at the end of the session. Note, unlike relations which are defined using the DEFREL command, there is no Nset definition for temporary relations. table 18 illustrates a how T1\_Arg is used to map a sequence of commands.

responsible for implementing them update the appropriate

### 3.5.2.5 Communication Databases

The final type of databases used by the External Level are databases used to communicate with the Nset level. These include INSERT\_ARG, DEF\_ARG, RET\_ARG, DV\_ARG, FV\_ARG, and DOM\_RET. Since these databases were described previously in our discussion of the Nset level, they will not be discussed here.

## 3.5.3 The Modules of the External Level

The External level is composed of 16 modules, as illustrated in Table 19 . With the exception of LEX and LEX2 each module corresponds to a command issued by the user and is responsible for implementing that command. When the user enters the system he is under the control of the SAM module, and is in the IFS environment. In this environment he can issue 2 commands, DEFINE and QUERY. These commands call the DEFINE and QUERY modules respectively. The DEFINE module sets up the DEFINE environment, in which the user may define domains, relations and views via calls to DEFDOM, DEFREL and DEFVIEW respectively. The QUERY module sets up the QUERY environment which, in fact, has 2 environments, the LOAD environment and the QUERY environment. The LOAD environment allows a user to enter data into a specified relation, whereas the QUERY environment allows a user to examine his database and issue relational operations against it. To move from one environment to another, it is necessary to return to the level which contains that environment, and then issue the appropriate command to invoke the environment. A null line will always return the user to the next higher level.

In this section we will briefly outline the purpose of each module and discuss its structure.

TABLE 19
SCHEMATIC VIEW OF EXTERNAL LEVEL

### 3.5.3.1 SAM

This is the entry point for the INFOSAM system and represents the outermost environment of the system. It has 2 roles. The first is to call NINIT which is required to initialize the Nset level. The second is to prompt the user to enter either the QUERY or DEFINE environments. If the user enters a null line at this level the procedure ends.

### 3.5.3.2 DEFINE

This module implements the DEFINE environment in which a user may define his database. The DEFINE module has 2 major tasks. The first task is to define the External level databases, RTABLE, DTABLE, and VTABLE if they have not already been defined. This is done by multiple calls to DEFINEV in order to define the domains of the relations DNAME, DATTR, RNAME, and ID), and then 3 calls to DEFINEN to define the Nset representations of the relations. The second task is to prompt the user for a valid DEFINE command and dispatch the appropriate routine. The support routine LEX is called to parse the user's response, and the routines are dispatched based on the key word starting the input string. If a user returns a null line, DEFINE returns to the IFS level. When the define modules (DEFDOM, DEFREL or DEFVIEW) return control to the DEFINE module, the DEFINE module prompts the user for a new command.

## 3.5.3.3 DEFDOM

This module processes the DOMAIN command which is used todefine a domain. The form of the DOMAIN command is as follows:

DOMAIN <dname> <d\_attr> where

<d\_attr>::= C <Len> | N <Len> <Min value> <max value>

Basically this requires it to perform 4 tasks. 1) If the user has not specified all the information necessary to process the request, the DEFDOM module must prompt the user for the additional information. 2) It must verify that no other domain has been defined with the same name. This is done via a call to FETCHV and requesting that it search the DNAME domain for an occurence of the name. If it is found, an error message is printed, and no further action is taken. Otherwise, the definition continues. 3) The next task is to format and insert the appropriate entry into DTABLE. This requires it to format the DATTR entry to reflect the domain characteristics, the DNAME entry to contain the name of the domain, and then set up the necessary call to INSERTN. 4) The final task is to call DEFINEV, passing it the name of the domain, so that the Nset level can issue the call necessary to define a Pset corresponding to that domain.

### 3.5.3.4 DEFREL

This module is responsible for processing the RELATION command which allows a user to define a relation. The format of this command is as follows:

RELATION <rname> <dname 1>....<dname i>

This requires DEFREL to accomplish 3 tasks, in addition to the task of prompting the user for any information required but not entered with the command. The first task is to validate the request. This takes the form of 2 checks. The first check is to verify that the relation name has not already been used. This is done via a call to FETCHV and having it search the RNAME domain. The second check is to insure that all domains specified are indeed defined in the system. This is accomplished via multiple calls to FETCHV, this time having it search within DNAME. If a domain name is not found in DNAME, the user is prompted to enter a new name. Once the request has been validated, the next task is to insert the relation definition into RTABLE. This is accomplished by multiple calls to INSERTN, passing it, via INSERT ARG the relation name and the domain name. Each domain in the relation will necessitate a call to INSERTN. The final task is to format DEF\_ARG to correspond to the relation being defined, and then to call DEFINEN in order to create the Nset definition for the relation.

### 3.5.3.5 DEFVIEW

This module is responsible processing the VIEW command which allows a user to define a view. The command form is:

VIEW <View Id> <rnamel> ...<rname i>

The tasks of DEFVIEW are very similar to those of DEFREL, except that no Nset definition is required. It must first validate the request. This consists of checking for the existence of a previously defined view with the same ID, once again accomplished via FETCHV except that it is requested to serach in the ID domain. In addition, DEFVIEW must check for the existence of the relations specified in the request. This is analogous to the checking for domains in DEFREL, except that the RNAME domain is checked. If the request is validated, then the view definition is inserted into VTABLE via multiple calls to INSERTN, where each call inserts a tuple with a different relation name.

### 3.5.3.6 QUERY

environment. It is called by issuing the QUERY command when at the IFS level. Once in the query environment, the user remains in that environment until he enters a null line while interacting with the QUERY module, which returns him to the IFS environment. The task of the QUERY module is to prompt the user for a valid QUERY command, call LEX to parse the response, and then if valid, dispatch the appropriate query routine. The dispatching is done by comparing the key

word in the user's response to an operator table, and calling the routine that matches. The logic is such that the user may also enter a 2 letter synonym for the command.

#### 3.5.3.7 GETVIEW

This module processes the GETVIEW or GV command which allows a user to access relations within a previously defined view. The command form is:

#### GV <View Id>

It has 3 basic tasks. The first task, as always, is request validation. In this case it must check for the existence of the view id specified in the request. This is done via a call to FETCHV to search the ID domain. If the ID is in fact found, the second task is to fetch the relation definitions (i.e. the RTABLE tuples) of relations within that view. This is done via a call to FETCHT, passing it a copy of RET\_ARG which in effect specifies that VTABLE is to be selected on the view ID, joined with RTABLE on RNAME, and the result projected over Dname and Rname. The third task is to build T1\_ARG based on the elements returned by FETCHT. As the reader will remember, each entry in T1\_ARG corresponds to a copy of RET\_ARG which if passed to FETCHT would retrieve the contents of the relation. Hence, GETVIEW must fill an entry

of T1\_ARG for each relation name returned as a result of the retrieval request. In addition, GETVIEW creates a table which contains the names of the relations contained in the view.

#### 3.5.3.8 SHVIEW

This module is responsible for processing the SHVIEW or SV command. This command allows a user to display the names of the relations contained in his current view. This module simply takes the table created by GETVIEW and prints it out. The command form is:

SV.

# 3.5.3.9 SHREL

This module processes the the SHREL or SR command which allows a user to see the domains and domain attributes of a relation defined in the current view. The syntax is:

#### SR <rname>

The module works in the following manner. It first verifies the request by checking the relation name specified against the names of the relations in the current view. This is done via the table created by GETVIEW. If the relation name is found then the corresponding entry in Tl\_ARG is located. For

each domain in the relation, FETCHT is called, passing it a copy of RET\_ARG which is set up to select DTABLE on DNAME = the domain name, and project the result on DATTR. This returns the attributes of the domain to SHREL which formats the attributes and prints them out along with the domain name.

# 3.5.3.10 SELECT

This procedure is responsible for processing the SELECT command. The form of the SELECT command is:

As described earlier this command is translated into a virtual operation on Tl\_ARG, and no data retrieval is done until a PRINT command is issued. The objective of the SELECT module is to create a new entry in Tl\_ARG which contains the information contained in the Tl\_ARG entry for Rnamel updated to reflect the select restriction on dname. Its first task is to verify that Rnamel exists in the current view. This is done by searching the REL table created by GETVIEW when the current view was loaded. If the relation is found, then it's corresponding entry in Tl\_ARG is found, and copied into the

next available entry in T1 ARG. Then, for each restriction specified in the request, the module locates the corresponding domain description in the T1 ARG entry for the new relation, and checks to see if it has an existing restriction placed on its value. If so, an error message is printed out. If not, the value specified in the request is inserted into the appropriate element in the entry, i.e. into T1\_ARG(i).RET INFO.VALUE(j,k), where i = the index of the rname2 entry in T1 ARG, j= Nset which contains domain, and k= index of domain within the Nset. If the new domain is not found an error message is printed out. The final task is to create a new entry in REL which contains the name of the new relation, rname2, and its index in the T1\_ARG database. If rname2=rname1 then REL is not updated.

### 3.5.3.11 PROJECT

This module is responsible for the virtual processing of the PROJECT command. The form of the command is :

PROJECT <rnamel> ON <dnamel>,..., <dname i> GIVING <rname2>
The logic of the project module is virtually identical to
that of the SELECT routine except that instead of placing
the restrict value into the appropriate element in the
T1 ARG entry for the new relation, the module sets the

appropriate elements in T1\_ARG to indicate that they are not to be retrieved. That is, the T1\_ARG(i).RET\_INFO.FETCH(j,k) fields of domains not specified in the command are set to indicate that those domains within that relation are not to be fetched.

#### 3.5.3.12 JOIN

This module is responsible for the virtual implementation of the JOIN command. The format of this command is as follows:

T1\_ARG(i).RET\_INFO.SAME(j,k) fields, where j and k specify the Nset and attribute pairs which correspond to the domains in rname2 on which the join is to be made. These fields must be updated to contain the index to the corresponding domains in rnamel. In addition, any RET INFO.SAME fields in the T1 ENTRY for rname3 must be updated to reflect the new position of the Nset definitions. For example, rname2 may have been created as a result of a join on 2 other relations. implement that join, the SAME fields for the common domains in the second relation would have been updated to specify the matching domains in the first relation (i.e. the SAME fields would appear as '0001xxxx'b where xxxx corresponds to the domain's index in the first Nset). However, when rnamel and rname2 are joined, the T1 ARG entry for the result will contain arguments for the Nset(s) which make up rnamel and for the 2 Nsets which make up rname2. Hence, the SAME fields for the domains which orginally implemented the join in the definition of rname2 must be changed to reflect that the 1st Nset of the rname2 component of rname3 is now the 2 Nset specified in rname3, i.e. the SAME fields must be changed to '0010xxxx'b.

#### 3.5.3.13 PRINT

This module is responsible for processing the PRINT command which allows the user to display the contents of any relation defined in his view, permanent or temporary. The format of the Print command is as follows:

#### PRINT <rname>

The PRINT module has 3 basic tasks. The first task is to retrieve formatting information for each domain specified in the T1\_ARG entry for the relation for which data is to be fetched. This is done by going through the domains specified in the Tl ARC entry for the relation, checking the FETCH field, and assuming it indicates retrieval, calling FETCHT to select the DTABLE on the domain name and to return the DNAME - DATTR tuple. The PRINT module then extracts the maximum length for the domain and places it in an array which is used to format the output line. The 2nd task is to retrieve the data elements contained in the relation as logically defined in the T1 ARG entry for the relation. This is accomplished by calling the FETCHT module and passing it the T1 ARG entry for the relation. FETCHT interprets T1 ARG and returns a stack of fixed length bit strings which correspond to the data elements found which met the restrictions specified in the Tl ARG entry. The final task is to print out

the retrieved data elements. This is done a tuple at a time. For example, if the relation contains n domains, the PRINT module takes the first n elements on the stack, uses the formatting information retrieved earlier to extract the relevant portion of each element, concatenates the resulting strings and prints them out. This continues until the stack is empty.

#### 3.5.3.14 LOAD

This module processes the LOAD command which allows a user to enter tuples into a previously defined permanent relation. The syntax is as follows:

# LOAD <Rname>

The LCAD command puts the user into a sub-environment of the QUERY environment, namely the LOAD environment. In this environment a user may continuously enter tuples into a relation, without having to enter LOAD each time. The LOAD module has 3 basic tasks to accomplish. The first task is to validate the user's request. This task is done in conjunction with the second task, namely the retrieval of the domain attributes for the relation specified. This is accomplished by calling FETCHT and passing it a copy of RET\_ARG which specifies that VTABLE is to be selected on the View

joined with RTABLE on RNAME, the result selected on ID, RNAME equal to the relation name specified in the request, the result joined with DTABLE on DNAME, and the final relation projected over DNAME and DATTR. If no tuples are returned then LOAD prints an error message. Otherwise, the tuples returned are put into a temporary copy of DTABLE, and a copy of INSERT ARG is initialized to contain the relation name as the Nset name and the domain names as the attribute names. Next, a header is printed out to specify the order in which values for the domains must be entered. The final task is to prompt the user to enter the tuples to be inserted. For each tuple entered, LOAD checks the values for each domain against the domain specifications in DTABLE. In particular it checks the data type, length, and if numeric whether the number is within the boundary values specified. If a value entered does not meet the criteria, error message is printed and the user is given a chance to re-enter that data value. Once the tuple has been validated, the domain values are inserted into INSERT ARG and INSERTN is called to insert the tuple specified in INSERT\_ARG into the Nset representation of the relation.

#### 3.5.3.15 LEXICAL ANALYSIS ROUTINES

There are 3 routines which are responsible the lexical analysis of command lines entered by the user. These are LEX, LEX2 and DELIM. LEX is the Primary lexical analysis routine. It performs 2 functions. The first function is to parse the command line into a token array, where each token is a character string of length 8. It recognizes commas, blanks and the equals sign as valid break characters, although the equals sign is also an operator. In addition, it allows a user to embed blanks in an argument if the argument is enclosed in quotes. This first task is accomplished by separating the input string into non-blank character strings separated by blanks. The non-blank character strings are put into the token array. The second task, which is done while the token array is being built, is to keep track of the position of key words in the command line. For example, AND, ON, GIVING, and =. The rationale for this is to simplify the interpretation task performed by the DELIM module.

LEX2 is a specialized routine which is only used by the LOAD module to parse the data values entered by the user. In this case a comma is required as a break charcter. LEX2 is very similar to LEX except that along with creating the tokens, it specifies the length of the character string con-

tained in the token. However, it is not concerned with the position of key words, since there are none.

DELIM is responsible for performing syntax checking of command lines issued within the QUERY environment. It is called by the QUERY module after LEX has lexically analyzed the input string, and after QUERY has identified the type of command. It is passed the type of command and the positions of the key words. The DELIM module then checks the position of the key words to see if they are positions that clearly imply an error in the command line. If so, the module makes an educated guess at the error, prints a diagnostic error message, and returns a a flag to the QUERY module to indicate that the command line is to be ignored.

# 3.6 CONCLUDING REMARKS ON THE EXTERNAL LEVEL

This concludes our discussion of the External level. Several points are worth noting. First, it should that clear from this discussion that the bulk of the External level's function is very much that of an interface. As such its major functions are, verifying the validity of user' commands, creating the necessary communication databases, and issuing calls to the Nset level to act on the contents of the communication databases. While only very rudimentary

data validity and security control functions were implemented, they are illustrative of a possible approach. Second, the implementation of the relational operators as virtual operations on essentially a mapping table is an interesting concept from a number of perspectives and probably warrants further thought. Third, the ability of the user to enter all or part of a command and be prompted for the rest, may seem trivial but it does add to the perceived flexibility and friendliness of the system.

# Chapter 4

# THE LESSONS OF INFOSAM

One of the primary objectives of the INFOSAM project was to develop a software test vehicle for the INFOPLEX functional hierarchy. The purpose of this software test vehicle was to gain further insight into the design of the functional hierarchy. While INFOSAM awaits a detailed performance analysis, the implementation itself, has several interesting implications for the design of the functional hierarchy. In this chapter we will discuss the implications of INFOSAM for the INFOPLEX project. In addition, we will suggest areas where the current implementation might be improved.

# 4.1 INFOSAM AND INFOPLEX - WHAT HAVE WE LEARNED

As a result of the process of implementing INFOSAM we gained some useful insights into the design of the INFOPLEX DBMS. In this section, we will address some of the key issues raised by this implementation of INFOSAM for the INFOPLEX DBMS concept.

INFOSAM suggests that the basic concept of the INFOPLEX DBMS, as proposed by Hsu, works. While it may be argued that INFOSAM is a pale version of the proposed system it does incorporate many of the key design aspects of the system. It is implemented as a functional hierarchy, it makes use of similar data models, and it performs the full translation from External view to the Primitive layer view. We have seen that the mapping process between levels is both possible and powerful.

From an implementation standpoint there is no doubt in my mind that the concept of a functional hierarchy greatly simplifies the implementation process. By building the system a level at a time, starting with the lowest level and working up, debugging was made much simplier since it could be done for each level individually. In addition, since the level's rely heavily on the functions provided by the levels beneath them, the levels became progressively quicker to implement and debug as much of the upper level's tasks were nothing more than calls to the lower level modules. The strategy of implementing a level's catalogues in term's of the level's data model also simplified the debugging phase. Since, the levels employed the same logic in managing their catalogues as for implementing user requests, once a level managed its

catalogues correctly , chances were that it could handle user requests correctly as well.

However, the implementation also raised some disquieting issues as well. For one thing, it was not until we started to implement the Nset level that it became apparent that a full implementation of the Nset level as proposed by Hsu would be extremely complex, if not nearly impossible. The generality of the proposed structure makes operations, even like insertion, very complex. This is particularly true if the operation involves 2 or more Nsets. This complexity wasn't readily apparent until we were faced with the problem of actually implementing it. Our response was to sidestep the issue and only implement a restricted form of the binary network. Hence, the Nset level as implemented here lacks much of the semantic richness that Hsu's design incorporates. However, Hsu's design would probably be a master's thesis in itself to implement.

A second point is that by the very nature of a functional hierarchy, modules in lower level's tend to be called on a great deal to support upper level functions. For example, the SEARCH module may be called upwards of 20 times just to support a given insert tuple command. If this were a multi-

threaded system we suspect that you would see a good deal of contention for key modules in the INTERNAL and NSET levels. In this implementation every attempt was made to avoid a redundacy of of function between the levels. In a later implementation it may make sense to examine this objective and see whether there may be functions which, in the interest of efficiency, are best duplicated across levels. One area where this might be true is in regard to the handling of system databases. The approach taken in INFOSAM is conceptually clean and appealing, but it may not necessarily be the most efficient.

# 4.2 POTENTIAL AREAS FOR ENHANCEMENT.

In this section we will briefly outline a few areas in which the current implementation of INFOSAM could be enhanced or improved. In some cases these areas represent changes in the current design, and in other cases these are areas which were not addressed in this initial implementation.

# 4.2.1 Changes in Design

As currently implemented, the BEU is a fixed length structure, consisting of a fixed length pointer array and a fixed length data area. This is highly inefficient in terms of storage utilization, and represents an area which probably should be changed. The change to a variable length pointer array and data area could be easily implemented via the REFER option in PL/1.

The current system implements chaining among elements of a subset via linear chaining. This may represent an area where the system should be changed, or atleast examined. However, there may be tradeoffs here depending on the relative frequency that single elements of the subset are retrieved versus retrieval of all elements.

The join process of the Nset level is also an area for potential improvement. Intuitively, we feel that the join process is basically analogous to searching a tree structure, and there is probably a more efficient way of doing this than the one that is implemented.

The External level modules currently have security and data validation functions embedded in them. It would probably make sense to create separate modules to handle both

functions. Since the validation and security requirements of the various modules are fairly similar, it would make sense to consolidate the functions into separate uni-function modules.

The current implementation of the External level treats the relations defined by the user somewhat differently than the system defined relations. In particular, information concerning user's relations is temporarily stored in T1\_ARG and all user issued retrieval requests and relational operations involve T1\_ARG. The system relations should probably be treated the same way. Two approaches might be taken. One might be to maintain a system copy of T1\_ARG, and all requests or relational operations on system relations would reference this table. Another approach would be as follows. When a user's copy of T1\_ARG is loaded, the system would additionally load the upper entries in T1\_ARG with the information required to retrieve the tuples in the system relations relevant to the user.

# 4.3 ADDITIONS TO THE SYSTEM

Perhaps the single most important addition to the system would be to allow it to read and write to disk. Currently, the system does not have this capability, which means that a user must redefine and load his database each time he uses the system. A possible intermediate solution would be to create an initialization file which contained both the commands and data necessary to create the database. By redefining SYSIN in the external level so that it references the initialization file, and by adding an ON ENDFILE block which redefines SYSIN to be the terminal when end of file is encountered, a permanent database could be simulated. Every time the system was executed it would initially read from the file until it reached the end of the file, at which point it would begin reading from the terminal. Hence, it would be as if a permanent copy of the database was stored.

Ultimately, however, the system should have the capability to read and write to disk. This could be done with relatively few changes to the existing code through the use of AREAS and OFFSETs. One approach would be to declare an AREA in which all storage allocations were to be made. In addition, all pointer declarations would be changed to OFFSET declarations referencing this area. Otherwise, the code

would not have to be changed. When the system was executed it would begin by reading in this AREA into storage. Prior to terminating a session it would be written back to disk. In this manner, INFOSAM could be modified without great difficulty to support a permanent database.

Another area of potential interest might be to implement the Nset level as orginally envisioned by Hsu. As mentioned ealier, its our sense that this project might be of the same magnitude as the whole of the current INFOSAM project. Our sense is that the insert and definition modules will have to be made far more sophisticated, while the retrieval logic probably won't have to be changed very much. It may also be that the binary level will have to be enhanced to treat a binary association between 2 entities somewhat differently than the binary association between an entity and an attribute. That is, in an CREATEB request, it may be desirable to be able to specify the instance of one of the domains by specifying an instance of a previously defined binary association which contains the element. Another area of interest here would be to determine an approach toward handling Nsets in which not all of the attribute values were given when it was created. Hsu's design supports this concept, but it isn't clear how it might be implemented.

Another area of potential interest would be to implement a deletion capability. Here there are two type of deletions with which to be concerned. The first, and easiest would be to support the deletion of binary associations. This would not be very difficult. If the association was 1 to 1, all that would have to be done is to update the appropriate pointer slots to null. Otherwise, if the binary association involved a subset, then it would be necessary to unchain the element from the subset, and set the appropriate pointer slot to null. By modifying the SEARCH module slightly, it could be set up to return a pointer to the BEU in the subset chain which points to the element to be deleted. This would allow you to unchain the element from the subset. The deletion of elements from primary sets is a more complicated issue since 1 element may be linked to a variety of other elements. One approach might be to set a flag in the BEU indicating that it has been logically deleted, and modifying the SEARCH routine so that it recognises that the element has been deleted. In addition, a list would be kept of all elements which had been deleted during a session. At the end of the session, a module would then go through to physically implement the deletion and its associated ramifications. The rationale for such an approach is that the deletion process

may be sufficiently involved that it may not be desirable, from the view of response time, to physically delete elements when the command is issued.

The provision of an update capability is another area which warrants work. It is also linked fairly closely with the deletion capability since much of the logic would be the same. Once again, the biggest problem would be the updating of an element which was in more than one binary association.

#### 4.4 CONCLUDING REMARKS

At this point the reader should have a clear picture of INFOSAM, its design, its relationship to the INFOPLEX project, and it's strengths and weaknesses. We have seen that it is a relational DBMS, which is designed around the complimentary concepts of a functional hierarchy and the ANSI/SPARC proposed design. We discussed its role in the INFOPLEX project as a software test vehicle whereby additional insights could be gained into the design of the INFOPLEX functional hierarchy through the implementation, performance analysis and future modification of the INFOSAM system. We then presented an overview of the design. Here we stressed the hierarchical decomposition of the system into levels, where a level was distinguished by a unique

conceptual view of the data, level specific databases, and modules which accepted calls in terms of the level's data model and translated them into requests to the next lower level, expressed in terms of that level's data model. We then took the reader through each level in INFOSAM, and described its data model, databases and modules. In particular, we showed how the level's mapped their data model onto that of the next lower level. Finally, we discussed the lessons we have learned so far from INFOSAM, both for the INFOPLEX project and for future implementations of INFOSAM.

It is the author's sincere hope that the INFOSAM system will prove as useful to others, in particular the INFOPLEX project, as the process of its implementation proved to me.

                  THE PROCEDURE BEGINS BY FILLING THE NCAT STRUCTURE WITH
   ....
                  THE CORPESPONDING ARGUMENTS PASSED TO IT BY DEF_ARG. THIS DEFO0230
   . . . . .
                                                                                      DEF 00240
                  INCLUDES: THE NSET NAME, THE NUMBER OF ATTRIBUTES,
   ....
                                                                                      DEF00250
                  THE NAME OF EACH ATTRIBUTE, AND WHETHER THE ATTRIBUTE
    . . . . .
                  HAS A 1 TO 1 RELATIONSHIP TO THE ENTITY NODE. IT THEN
                                                                                      DEF 00260
                  CALLS DEFINED TO DEFINE A PSET WHICH CORRESPONDS TO
                                                                                      DEF00270
                  TO THE ENTITY NODE. THE ENTITY NODE IS GIVEN THE NAME
                                                                                      DEF00280
                  OF THE MSET, IS LINKED VIA HASHING, AND HAS A 32 BIT KEY. THE NEXT STEP IS TO CREATE BSET DEFINITIONS BETWEEN
                                                                                      DEF00290
    . . . . .
                                                                                      DEF00300
                                                                                      DEF00310
                   THE ENTITY HODE AND IT ATTRIBUTES. FOR EACH ATTRIBUTE
                                                                                      DEF00320
                   IT DETERMINES IF A I TO 1 OR A N TO 1 LINK IS TO BE
                   DEFINED BETWEEN THE ENTITY NODE AND ATTRIBUTE. IT THEN
                                                                                      DEF00330
                  CALLS NAMEGEN TO CREATE A NAME FOR THE BSET, AND THEN DEF00340 CALLS DEFINED TO CREATE THE BSET DEFINITION. IN ADDITION, DEF00350
                                                                                      DEF00360
                   IT CALLS DEFINER USING THE EQUIVALENT OPTION TO DEFINE
                                                                                      DEFC0370
                   THE RECIPROCAL LINK (I.E. BETWEEN THE ATTRIBUTE AND THE
                   ENTITY NODE). ONCE THIS IS DONE IT UPDATES NCAT TO REFLECT DEF00380
                   THE BSETS CREATED. FINALLY IT USES THE INFORMATION IN NOAT TO FILL INSERT ARG, AND CALLS INSERIN, PASSING IT
                                                                                      DEF00390
                                                                                      DEF00400
                   INSERT_ARG, TO CREATE AN ENTRY IN THE NSET CATALOGUE.
                                                                                      DEF00410
                                                                                      DEFO0420
                   CORRESPONDING TO THE MSET DEFINITION CREATED BY DEFINEN.
                                                                                       DEF00430
                                                                                      DEF00440
                                                                                       DEF00450
             INPUT PARAMETERS:
```

```

        VALUES FOR THE NSET NODE ARE FETCHED AND PLACED IN
                                                                 FE100570
        NLIST(I). THIS PROCESS IS REPEATED FOR ALL OF THE NSET FET00580
        SPECIFED IN RET_ARG. AT THE CONCLUSION OF ALL THIS
                                                                 FET00590
        NLIST WILL CONTAIN ONLY THOSE NODES WHICH MEET THE
                                                                 FE100600
        SELECT CRITERIA IN RET_ARG.
                                                                 FE100610
     4) THE NEXT TASK IS TO PERFORM ANY JOINS WHICH HAVE BEEN FET00620
        SPECIFIED. THIS IS ACCOMPLISHED BY CALLING NUDIN1 WHICHFE100630
        IS RESPONSIBLE FOR HANDLING JOINS. NUOINI IS PASSED
                                                                 FE100640
        THE NUMBER OF NSETS INVOLVED, AND BECAUSE NLIST AND NCATFET00650
        ARE DEFINED TO BE EXTERNAL NUCINI HAS ACCESS TO THEM ASFE100660
        WELL. NJOINI RETURNS A STACK(CTL) CALLED TUPLE WHICH
                                                                 FFT00670
        CORRESPONDS TO THE NSET NODES WHICH SATISFY THE JOIN.
                                                                 FE100580
        IF ONLY ONE NSET HAS BEEN SPECIFIED, FETCHT DOES NOT
                                                                 FET00690
        CALL NUCINI BUT RATHER BUILDS TUPLE ITSELF.
                                                                 FE100700
     5) THE NEXT STEP IS TO RECTANGULARIZE THE NSET NODES SO
                                                                 FF100710
        A TABLE CAN BE CREATED. THIS TASK IS PERFORMED BY TABN FET00720
        WHICH USES THE TUPLE STACK (ALSO DEFINED AS EXTERNAL)
                                                                 FE100730
        TO CREATE A TABLE CALLED TAB, WHERE EACH ENTRY IN TAB FE100740 AN NSET NODE. UNLY THOSE NODES WHICH MET BOTH THE SELECTFE100750
        AND THE JOIN RESTRICTIONS ARE CONTAINED IN TAB.
                                                                 FE100760
     6) THE LAST STEP IS TO FETCH THE ACTUAL ATTRIBUTE VALUES
                                                                 FET00770
        WHICH ARE LINKED TO THE NODES IN TAB AND WHICH ARE
                                                                 FE100780
        REQUESTED IN RET_ARG (I.E. FOR WHICH RET_INFO.FETCH
                                                                 FET00790
         '1'B). THIS IS ACCOMPLISHED BY GOING THROUGH TAB A ROW FETOOBOO
        AT A TIME AND USING SELECTE TO FETCH THE ATTRIBUTE

   THE DEFINEP PROCEDURE, PASSING IT THE NAME OF THE
                                                               F0R00500
   PSET CONTAINING THE SUBSET ( I.E. DOMAIN2), AS WELL AS FOROOS10
   THE POINTER SLOT ALLOCATED BY THE DEFINEB PROCEDURE
                                                               FOR00520
   TO BE USED FOR CHAINING ELEMENTS OF THE SUBSET TOGETHERFORO0530
   THE DEFINEP PROCEDURE RETURNS A POINTER TO THE CATALOG FOR00540
   ENTRY CREATED AND THIS POINTER IS PLACED IN AP POS
                                                               FOR00550
   (1) OF THE BEU CONTAINING DATAL IF THE POINTER SLOT
                                                               F0R00560
   WAS ORGINALLY NON-NULL THEN IT ALREADY POINTED TO THE
                                                               FOR00570
   CATALOGUE ENTRY. THE NEXT STEP IS TO CHAIN DATA2 TO
                                                               FOROOSRO
   DATA1.THIS CONSISTS OF SEVERAL TASKS. FIRST GET_DOMAIN2FOR00590
   IS CALLED AND IT EITHER FINDS AN ELIGIBLE OCCURENCE
   OF DATA2 IN DOMAIN2 AND CHAINS IT INTO THE SUBSET, OR FOROOG10 IT CREATES AN OCCURENCE OF DATA2 WITHIN THE SUBSET THIS FOROOG20
   ALSO HAS THE EFFECT OF INSERTING IT INTO DOMAIN2. IN
                                                               F0R00630
   EITHER EVENT IT RETURNS A POINTER TO THE BEU WHICH
                                                               FOR00640
   CONTAINS DATA2, AND CREATEB UPDATES THE AP POS(2)
                                                               FOR00650
   POINTER SLOT POINTED TO BY THAT POINTER TO POINT TO THEFOROGGO
   OCCURENCE OF DATA1 IN DOMAIN1.
                                                               E0800670
5) IF THE BSET IS N-1 THE LOGIC IS VERY SIMILAR BUT IN
                                                               FOR00680
   REVERSE. IT FIRST CHECKS TO SEE IF AN OCCURENCE OF DATAFORO0690
   EXISTS, AND IF NOT IT CREATES AN OCCURENCE OF DATA2. IT FOR00700
   THEN CHECKS TO SEE IF THE AP POS(2) POINTER SLOT IN THEFOROO710
   BEU CONTAINING DATA2 IS NULL OR NOT. IF SO, IT IS
                                                               FOR00720
   NECESSARY TO CREATE A CATALOGUE ENTRY FOR THE SUBSET
                                                               FOR00730
   10 BE CREATED IN DOMAIN1, AND THIS IS ACCOMPLISHED VIA FOR00740
   A CALL TO DEFINEP. IF IT WAS NECESSARY TO CREATE THE
                                                               FOR00750
   CATALOGUE ENTRY THEN THE AP POS(2) POINTER SLOT OF DATAFOR00760 IS UPDATED TO POINT TO 11. THE PROCEDURE THEN CHAINS FOR00770
   THE OCCURRENCE OF DATA! INTO THE SUBSET, AND UPDATES
                                                               FOR00780
   THE AP POS(1) POINTER SLOT WITHIN THE BEU CONTAINING DATA! SO THAT IT POINTS TO THE OCCURENCE OF DATA2.
                                                               FOR00790
                                                               FOR 00800
6) IF THE BSET IS M-N THE FOLLOWING STRATEGY IS FOLLOWED: FOR00810
   A) IT FIRST CHECKS TO SEE IF THE AP_POS(1) POINTER SLOT FOROUB20
     IN DATA1, IS NULL OR NOT. IF IT IS THEN IT CALLS
                                                               F0R00830
     DEFINEP TO CREATE A SUBSET WITHIN THE PSET IDENTIFIEDFORO0840
     BY MN NAME AND WHICH ACTS AS A LINK SET BETWEEN
                                                               FOR00850
     DOMAIN1 AND DOMAIN2. IT THEN UPDATES THE AP_POS(1)
                                                               F0R00860
     POINTER SLOT SO THAT IT POINTS TO THE SUBSET
                                                               FOR00870
     CATALOGUE DEFINITION.
                                                               FOROOBHO
   B) IT THEN CREATES AN ENTRY IN THE SUBSET OF THE LINK
                                                               FOR00890
     SET VIA A CALL TO CREATEP (NOTE THIS ALSO CREATES
                                                               F0R00900
     AN ENTRY IN THE PRIMARY LINK SET PSET.
                                                               FOR00910
   C) IT THEN CALLS GET_DOMAIN2 WHICH EITHER FINDS AN
                                                               FOR00920
     ELIGIBLE OCCURENCE OF DATA2 IN DOMAIN2 OR 1T CREATES FOR00930
```

A NEW OCCURENCE, AND IN ANY EVENT RETURNS A POINTER FOR00940

```
....
                           TO THE OCCURENCE OF DATA2.
                                                                                FOR00950
                         D) THE FINAL TASK IS TO CHAIN THE NEWLY CREATED ENTRY
                                                                                FOR00960
          ....
                           IN THE LINK SET SUBSET WITH DATA1 AND DATA2. THE AP_POS(1) POINTER SLOT OF THE ENTRY IS UPDATED TO
                                                                                FOR00970

                                                                         DEF00440
             WPENEVER THE CATALOGUE ENTRY IS REQUIRED, THE BEU WHICH
                                                                        DEF00450
```

....

....

```
DEF00460
CONTAINS IT IS FETCHED AND THE CAT ENTRY STRUCTURE IS
OVERLAID ON DATA PORTION OF THE BEU. THE FOLLOWING
                                                                DEF00470
                                                                DEF00480
STRATEGY IS EMPLOYED TO CREATE THE CATALOGUE ENTRY
A) IF THIS IS THE FIRST PSET TO HAVE BEEN DEFINED IT
                                                                DF F00490
   IS FIRST NECESSARY TO CREATE THE P CAT PSET. A
                                                                DEF00500
   MODULE CALLED INIT P (INTERNAL TO DEFINEP) IS RESPONSIBLE FOR THIS. INIT P ESSENTIALLY CREATES
                                                                DEF00510
                                                                DEF00520
   A BEU WHICH CONTAINS THE P_CAT CATALOGUE ENTRY FOR
                                                                DEF00530
   THE P_CAT PSET, AND THIS BECOMES THE FIRST ENTRY IN
                                                                DEF00540
                                                                DEF00550
   THE P CAT PSET. THIS ENTRY CONTAINS INFORMATION ON
   HOW THE P_CAT PSET IS TO BE ORGANIZED. IN ADDITION, INIT_P CREATES A SCATTER TABLE FOR THE P_CAT PSET.
                                                                DEF00560
                                                                DEF00570
B) THE NEXT STEP IS TO RETRIEVE A TEMPLATE FOR THE NEW CATALOGUE ENTRY. IF THE PSET TO BE DEFINED IS A SUB-
                                                                DEF00580
                                                                DEF00590
   SET OF ANOTHER PSET, THEN A POINTER TO THE CATALOGUE
                                                                DEF00600
   ENTRY FOR THAT PSET IS RETRIEVED VIA THE SEARCH
                                                                DEFORGED
   ROUTINE. OTHERWISE, THE SEARCH ROUTINE IS CALLED TO
                                                                DEF00620
   RETURN A POINTER TO THE P_CAT PSET CATALOGUE ENTRY.
                                                                DEF00630
   THE OBJECTIVE HERE IS THAT IF THE PSET IS A SUBSET OF ANOTHER PSET THEN ITS CATALOGUE ENTRY MUST REFLECT
                                                                DEF00640
                                                                DEF00650
   THE ORGANIZATION OF THE PSET OF WHICH IT IS A SUBSET.
                                                                DEF00660
C) IN EITHER CASE, THE INFORMATION IN THE BEU POINTED
                                                                DEF00670
   TO BY THE POINTER RETURNED IN (B) IS COPIED INTO A
                                                                DEF00680
A TEMPORARY STRUCTURE CALLED CAT ENTRY.

D) IF THE PSET BEING DEFINED IS NOT A SUBSET THEN CAT
                                                                DEF00690
